I think the case of a concentrated load such as a balun and feedline,
along with a distributed load is also exactly solved by a catenary,
just the ends are at unequal heights. The three dimensional nature of
the problem when horizontal wind forces are considered as well as
vertical weight forces makes solutions messy.

>should not be over one fourth this [ultimate breaking strength]."

Now that it is so easy to calculate the catenary, it is the way to
go.. but on shallow catenarys of equal height, the solution is not
much different to a parabolic one. There is still a computational
advantage to the parobolic approximation.

Standards here (aka "codes" in your country) stipulate the safety
factor to be used, and it is 3.5 for standing rigging, 5 for running
rigging. That does apply to guy wires, and seems appropriate to
antenna wires that may not also be guy wires.

I note that the ARRL takes a different approach. The ARRL Antenna
Handbook 18th edition has some information on sagging wire antenna
spans on pages 20-2ff. Similar information may be in other editions.

There is no explicit discussion of wind loading, and the design guides
(tables, nomographs, text) lead the reader to a design based on
weight loading alone and with a Safety Factor of 10 or 5 depending on
the chosen tension.

I guess that approach supports the maxim that "if your antenna didn't
blow down last season, it wasn't gib enough", or am I mythtaken!

If the rope stretches more easily than the metal conductor, it may
(depending on how it is supported) increase the tension in the metal
conductor and break it.

> -----
> Reg, G4FGQ.

Hello, and the present or absence of reflections in the steady-state (no transients as one would see when the system is first energized) is by comparison of an impedance (Zx) at a measurement point to some reference impedance (Zo). This reference impedance can be associated with the characteristic impedance of a transmission line or some other system characteristic. If Zx and/or Zo varies with frequency (has a reactive component) then the RMS amplitude of the voltage/current reflections also varies with frequency. We use this property to match Zx to Zo at some frequency by minimizing the measured reflected voltage (or current or power).

In the steady-state there is one voltage/current (as seen by an RF voltmeter or ammeter) placed at the measurement point. We need a directional coupler (part of a Bird model 43) or impedance bridge (referenced to Zo) inserted at the measurment point in order to partition the sampled voltage/current into incident (forward) and reflected waves. I'm not sure exactly what Reg meant. Sincerely, and 73s from N4GGO,

The versions in Ubuntu Edgy and Debian Etch both hang at the splash screen. I asked on the Wine mailing list, but nothing helpful turned up. I can run it under VMWare - slow on my machine -, or I can use the kids' Windows game computer. But the gap between their bedtime and mine is closing.

The Wine people are interested in fixing bugs, but they need info from app developers. Roy, would you be interested in working with them, if I can get a Wine developer interested?

What toolkit do you use?

Regards

LA4RT Jon

>a-d-i-o-s. You don't need to know what it means.

When it's spoken very quickly and in a panic, it's more like
"adhyose". Understandable, if weird looking, to a Spaniard. Try some
other languages, though - those you've never heard spoken before. See
how well you do. Then see how well you do in CW ... oh, you already
know that, don't you? -.-. is the same, whether it's hard, soft or
unpronounced. Whether you put a cedilla on it or not, a Spaniard will
understand it. So will a Turk, even though it sounds more like - -.-.
But would you write "Con" for something that sounds like Tchonn?

Hi John, one important fact that some people would like to
forget is that the reflected wave can indeed be partitioned
from the forward wave. Some people on this newsgroup argue
that the forward wave and reflected wave are inseparable and
that reflected waves contain no rearward traveling energy.

However a circulator plus load resistor located at the source
will prevent reflected wave energy from being incident upon
the source and will heat up that load resistor in the process
proving that reflected waves are real and do contain energy.

My favorite illustration of such is a one-second lossless
transmission line with reflections. The number of watts in
the forward wave plus the number of watts in the reflected
wave equals the number of joules stored in the line during
steady-state. For instance, if Pfor = 200w and Pref = 100w,
then 300 joules of RF energy exist in the one-second long
lossless line during steady-state.

I can certainly write down Spanish spoken at my CW
speed of 13 wpm which is the whole point. If one speaks
faster, I may not be able to copy it. If one sends CW
to me faster than 13 wpm, for sure I cannot copy it even
in English.

Hello, and it would be more correct to say that the forward and reflected waves are components of a standing wave.

> However a circulator plus load resistor located at the source
> will prevent reflected wave energy from being incident upon
> the source and will heat up that load resistor in the process
> proving that reflected waves are real and do contain energy.

Hmm. Don't quite get that. Say an RF voltage source is located at port A of an ideal 3-port circulator designed for a system (characteristic) impedance of Zo. A load of ZL terminates port B and a load of Zo is attached to port C. Now, incident energy from the source at A is transferred by circulator action to the load at port B. If ZL is not equal to Zo then reflected energy from port B is transferred to port C where it is dissipated in the port C termination. None of the reflected energy originating from port B ever returns to port A in this ideal case (circulator has infinite isolation). Sincerely,

> to mention that it can handle complex numbers.

Still thinking about the scripting languages, but wanted to finish the
analysis
with Excel. While trying to set up the "Cross product matrix" I
ran into a major formatting problem with Excel. When I convert
the polar form of a complex number (two cells) to rectangular form
(single cell); the cell size expands to 42 digits in scientific format.
The problem lies in the fact that Excel treats complex numbers as
text, and they cannot be formatted in the normal way. I have
searched several bookstores, and looked at every major book
on Excel, and VBA macros. Complex numbers are treated in only
a superficial way, or not at all.

Microsoft does discuss the problem concerning XL2000 at:
http://support.microsoft.com/?kbid=213294
The VB code does not make a lot of sense to me, also in particular
the statement: "=FormatComplex(A1,"0.00","0.0000")" does not
appear to work, nor does their "Sample VBA Procedure". This may
be due to the fact that I am using Excel 97.

Anyway, this is not really the forum for this discussion, but others
attempting to deal with the NEC output file analysis, may have
some ideas. It looks like it may be some time before I can
arrive at any results -- probably with some scripting code.

Frank

Home Depot, Lowes, or any other local Borg...
I've been using ordinary, stranded 12 guage THHN house wiring. It's insulated (yes, you do need to adjust length a bit for the insulation), comes in a variety of colors (I prefer black or blue) and is strong enough for most any antenna you'll likely put up. With fixed corner posts, I ran a 800 foot loop through and over trees without any problems, and have run at least one 160M half wave without any issues. Note that I'm not in a heavy icing area, as my temperatures rarely get even close to freezing where I live now (Hawaii), but many others have also used stranded household wire to good effect. If your antenna isn't in the clear, the insulation helps. Given a tree on one end, I've used a pulley at the top with a rope connected to the antenna end, with a bucket of sand on the other end. The bucket moves up and down as the tree moves, and the last time I used this approach (in Washington state) the rope lasted 5 or 6 years before I needed to replace it.

Good Luck,

The conduits (bus ducts) don't get hot mainly because they have greater total cross sectional area than the bus itself. They're about a half inch thick aluminum and maybe three feet in diameter. All joints are continuously welded.

Some documents I've found suggest 95% shielding efficiency, supposedly less than 100% due not to skin effect, but to resistivity.

Regarding the other responder's comments on jewelry and so on, here's my anecdote. Not so long ago I climbed up near the main generator output bushings to view a cooling air damper through a window in the housing. This is sort of unusual with the plant at power and it made me a bit nervous. I stayed about five minutes, but after I climbed down I discovered that my (analog) watch had gained an hour!

Now I can't find that watch. My theory is that it's off in the future just an hour out, but I can't catch up to it.

Hi Cecil

How much energy is "in the reflected wave" without a circulator load
resistor?

It's worth pointing out that copperweld, in addition to being superior
to house wiring, is CHEAPER than solid copper at the moment.

Out here on the Left Coast, when one wants "The Best" in antenna wire,
one goes to a Marine Hardware supplier and orders PhospherBronze
Antenna Wire. This is used on most Vessels as LF/MF/HF Antenna Wire.
It lasts, basically forever, withstands whipping, doesn't stretch,
and is corrosion resistant in almost any weather or sea condition.
It comes in various sizes from #12 (7/12) on up to Ought (O) depending
on your antenna current and rigging. Standard NecoPress and Splitbolt
Hardware in PhosherBronze is available to facilitate rigging. I think
if you look on just about ANY Military Vessel, if it has wire antennas
they will be spec'd as PhospherBronze. It isn't cheap, but it is
"The Best".....

There's the same amount of energy in the reflected wave
either way, with or without a circulator load resistor.
The reflected wave is incapable of looking ahead and
using its free will to decide how much energy to contain
depending upon its future fate. But that is what some
people would have us believe.

Does your question imply: A reflected wave that is
going to be dissipated in a circulator resistor sometime
in the future contains energy but a reflected wave that
is going to be dissipated after the power is turned off
does not contain energy?

In a one second long lossless transmission line, watts
equal joules. A forward wave of 200 watts contains 200
joules of energy. A reflected wave of 100 watts contains
100 joules of energy. Under such conditions, the source
has supplied exactly 300 joules more than has been
delivered to the load, no more and no less. Conservation
of energy strikes again.

The question implies that there are issues regarding the flow of
energy which you continue to misunderstand. Your answer confirms this.

The person who reported the problems posted them on the appropriate newsgroup but as far as I know got no response. The primary problem is that the manual can't be viewed under wine, and the last thing I want is to have the program functional but the manual not functional. Only when that problem is fixed will I address any others. The manual is created with RoboHelp v. 7, and although getting pretty old now, it's always worked on all Windows systems as well as under Mac emulators. The manual is EZW4.hlp with EZW4.cnt, which are installed with the EZNEC demo program and freely available for analysis by anyone who's interested.

This isn't the appropriate newsgroup for this discussion, so we should take this discussion off-line for any followup.

So please enlighten me. How does a wave know whether to
carry energy or not depending upon its future fate? It
is my understanding that the power in an EM wave is ExH
no matter what its future fate.

Does a laser beam reflected from an ideal mirror carry any
less energy than the forward beam just because it has been
reflected? If so, how does that not violate the conservation
of energy principle?

Yes, in both cases the voltage reflection coefficient
at the load is 0.707 making the power reflection
coefficient = 0.5, i.e. half the power incident upon
the load is reflected.

The system with the circulator load at the signal
generator has the signal generator supplying 200
watts and the circulator load resistor dissipating 100
watts. 'SGCR' stands for a signal generator equipped with
a circulator and circulator load resistor equal to the
Z0 of the feedline. There's 300 joules of energy in the
feedline during steady-state. 100 watts is dissipated
in the load.

200W SGCR-----one second long feedline-------load
Pfor=200W--> <--Pref=100W

The system without the circulator and load consists of
a 100 watt source feeding an ideal autotuner tied to
the transmission line. In this case all reflected energy
is re-reflected by the Z0-matched autotuner. 'SGAT' stands
for a signal generator equipped with an ideal autotuner.

There's 300 joules of energy in the feedline during
steady-state. 100 watts is dissipated in the load.

100W SGAT-----one second long feedline-------load
Pfor=200W--> <--Pref=100W

Since reading Rick's post I should add that I have the two extra elements for six and have had great success.
I cannot compare it to another antenna, but I just got a 6M QSL from New Hampshire and I'm in Texas.

> the load is reflected.

But, is the latter really more than a mathematical convenience? (You
may recall that 'power' isn't something which actually moves in
physical systems. And being a scalar, it can be tricky to do a proper
vector analysis.) How energy moves is dependent upon factors
throughout the entire system - not just at the load.

> The system with the circulator load at the signal

> 100W SGAT-----one second long feedline-------load
> Pfor=200W--> <--Pref=100W

Very inventive. The question was posed without a load on the circulator, not without a circulator. You still haven't answered that question. Perhaps you wouldn't mind just considering one system at a time. No sense changing the variables just to make the solution come out the way we want. Don't they teach you that you're not supposed to change horses in the middle of a stream out there in Texas? ;-)

So, since we've obviously been talking about the steady state, what's with all the weird questions about 'how the wave knows' what's going to happen in the future?

Oh, oh...in the PC (Political Correctness) of morsedom,
the code test cannot possibly ever be a "barrier."

ALL "good hams" should WORK for their AMATEUR licenses!

Those that won't are worse than river-bottom slime...:-)

Trying to speak logically, the FCC grants amateur licenses
in the USA and even they proposed (via an NPRM) to eliminate
the amateur radio morse code test for a license. FCC is on
record of a couple decades ago that this singular manual
skill test does not tell them if a license applicant is
worthy of a federal license.

That's also a symptom of anoxia...lack of oxygen used up in
his bragging of what he did that never was... :-)

Tsk, all that work he does in trying to bluff us. All he had to
do was present SOME sort of document proof or even a personal
snapshot taken while in that "hostile-action-filled" 18 year
"career" in the USMC. He hasn't done so after many years.

If he can't present a single item of 18 years of his life, it
is hard for the rest of us to believe anything he said.

Your objection was that I cannot write Spanish at 100 wpm.
I admit that but I know how to say "despacio" until they
slow down so I can write it down. Since I can copy CW
at 13 wpm, that seems to be a reasonable comparison.

Actually, I am struggling to understand your concepts which
you appear somewhat incapable of putting into words, hence
the total absence of anything technical in your posting.

Is energy-passing-a-point "power" as defined by the IEEE
Dictionary? Does an EM wave possesses ExH amount of power
as the technical references assert?

> So, since we've obviously been talking about the steady state, what's
> with all the weird questions about 'how the wave knows' what's going to

Steady-state had a beginning and it will have an end. It
cannot be analyzed without knowing what happened in the
beginning and what will happen in the end. Steady-state
is the rug under which you and others try to sweep the
laws of physics including the conservation of energy
principle. I'm doing what I can to call your bluff.

Hi Jim,

I don't know how you can pass up all these tarnished jewels.

Energy at the speed of light has no time dimension (Lorenz law) and as
such there is no futurity. No future, no fate - presumptions aside
(or galore, depending upon the source).
>
>> Does a laser beam reflected from an ideal mirror carry any
>> less energy than the forward beam just because it has been
>> reflected?

Of course it does.

Jim, your question was:

>How much energy is "in the reflected wave" without a circulator load
>resistor?

and we find, after having gone down the primrose path:

>> Yes, in both cases the voltage reflection coefficient
>> at the load is 0.707 making the power reflection
>> coefficient = 0.5, i.e. half the power incident upon
>> the load is reflected.

The common finding of an unterminated circulator load would offer
reflections from that port passing back to the apparent source, the
original mismatched load. Hence, that load sees more than 0.707
(whatever) - now from two "sources."

There is one way to prevent this, but Cecil doesn't have enough
experience at the linear bench to come up with that solution.
Certainly I can anticipate his fog of vectors and SWR mechanics with 1
second transmission lines blossoming in the swamp - but a real bench
tech could whip out the solution and make it work with less effort and
certainly not have to cobble up a phonebook thick stack of Xeroxed
proofs.

>Very inventive. The question was posed without a load on the
>circulator, not without a circulator.

You were expecting something else? ;-)

Stranded phosphor bronze is also the normal antenna wire for North Sea fishing trawlers, which regularly experience strong gales and heavy icing in Arctic waters.

A G3 who lives on the Right Coast of the UK has 80m and 40m inverted-Vs made from 3/8in fozzy bronze, and those antennas are also his tower guys.

Oh, oh...in the PC (Political Correctness) of morsedom,
the code test cannot possibly ever be a "barrier."

ALL "good hams" should WORK for their AMATEUR licenses!

Those that won't are worse than river-bottom slime...:-)

Trying to speak logically, the FCC grants amateur licenses
in the USA and even they proposed (via an NPRM) to eliminate
the amateur radio morse code test for a license. FCC is on
record of a couple decades ago that this singular manual
skill test does not tell them if a license applicant is
worthy of a federal license.

Hi,

This is a variant on a question I asked a couple days ago. Again I'm not the most hardware knowledgable so apologies in advance.

I have two WiFi (802.11b here) routers that I'm using to conduct some experiments. They will be co-located (~half wavelength spacing) and sending broadcast packets in a continuous loop over the duration of the experiment. I originally wanted to disable carrier sense on the routers so that they could transmit packets simultaneously. Given the difficulty I've had trying to achieve this as an alternative I would like to use some sort of timed switching device. Essentially I would like this device to on each clock cycle short one of the routers to its respective antenna and open circuit the other router from its antenna and ground its output, and then on the next cycle do the opposite. I'd like a clock period of about 2 msec. The idea then would be that the routers would not block one another from transmitting.

One might ask why not just let them both transmit without this switching device, in theory the carrier sense should allow equal channel use, but I've observed that its not as evenly distrubuted over time intervals as I would like for my experiments. Thanks for any suggestions on this device,

Kev

> experience at the linear bench to come up with that solution.

Probably true but I am not looking to solve that non-problem.

The question to be answered is: Is the power in an EM wave
equal to ExH as the textbooks say, or is it zero until
dissipated? Jim obviously has his own personal definition of
"power" that disagrees with The IEEE Dictionary. That is
what he is basing his entire argument on - simple semantics
using special definitions of words.

That's why my argument involves one second long transmission
lines in which power in watts = energy in joules. That's
an argument that is very difficult to sweep under the rug.

The number of joules in a transmission line *ALWAYS* equals
the number of joules not lost to radiation, I^2R, and
dielectric and not yet delivered to the load. And it is
ALWAYS equivalent to the sum of the forward and reflected
powers in that particular length of transmission line.

As I said in another post, try that in Turkish. Or Latvian. Or any
other language you don't know a single word of.

But in CW, it doesn't matter - you write the letters as they come,
whether you know what they mean or not. In the Navy, we had to read
what we had copied to know what it said - the CW came in your ear and
went out your fingers, you didn't pay attention to it. English? Who
knew, until you read it?

> Dictionary? Does an EM wave possesses ExH amount of power
> as the technical references assert?

Nothing the IEEE says counters the fact that the mathematical product of two physical quantities does not and can not physically propagate through a transmission line. It can also not reflect, refract, diffract, superpose, or interfere constructively or destructively. Waves propagate and energy moves. Power is simply the rate at which energy is transferred or changes form. It is the rate at which 'electric smoke' is liberated from one's aerial so to speak.

> Steady-state had a beginning and it will have an end. It
> cannot be analyzed without knowing what happened in the
> beginning and what will happen in the end.

But there's no dispute about what happens in the beginning or at the end. It's entirely about what you claim is happening in the steady state.

> Steady-state
> is the rug under which you and others try to sweep the
> laws of physics including the conservation of energy
> principle.

The steady-state condition isn't something which contradicts nature - it IS nature. Clearly, the only one needing to sweep the laws of physics under the rug around here is you, Cecil.

Cecil,

Countless mathematicians and scientists would disagree with your characterization of steady state. Perhaps even a few engineers as well. 8-)

This sort of stuff is thoroughly covered in differential equations courses and in any physics or engineering course that look at electrical or mechanical response to impulses and other stimuli. Surely they dealt with such matters at TAMU.

If you refuse to accept standard technical conventions, then there is little hope of getting others to agree with you.

Once again you make a statement with which no one has disagreed.
Has anybody in the world said otherwise? I certainly have not,
so your statement appears to be just another one of your straw
men. Energy flowing past a point is defined as *power* at that
fixed point even if it is reflected energy! The fact that you are
forced to misrepresent what I have said speaks volumes.

> But there's no dispute about what happens in the beginning or at the
> end. It's entirely about what you claim is happening in the steady state.

Exactly what is my claim about what is happening in the steady-
state? In case you misunderstood, here it is again.

What I have said is happening during steady-state is that the
source has supplied exactly the amount of energy contained in
the measured forward wave and the measured reflected wave. That
energy has been delivered to the system by the source but has
not yet reached the load. Occam's razor says that exact amount
of energy is most likely contained in the forward and reflected
waves, not magically somewhere else, e.g. sloshing around between
standing wave nodes as W7EL asserts.

I say the ExH watts exist in the forward wave and the reflected
wave just as the textbooks assert. You seem to be saying that it
isn't there. If it isn't there, where did it go? Conservation of
energy strikes again.

Gene, have you stopped beating your wife? Your usual ad
hominem attack completely devoid of any technical content
is duly noted.

In a one second long lossless transmission line where the
forward power is 200W and the reflected power is 100W, it
can be proved that the source has supplied 300 joules that
have not been accepted by the load. If those joules are not
contained in the forward and reflected waves, where are they?

I am advocating the wave reflection model as explained in:

Johnson's, "Transmission Lines and Networks", 1st Edition

Ramo/Whinnery's, "Fields and Waves in Modern Radio", 2nd Edition

Hecht's, "Optics", 4th Edition

Maxwell's, "Reflections" and "Reflections II"

"The ARRL Antenna Book", 15th Edition

I am also advocating the conservation of energy principle.
I hope that one doesn't need references.

Exactly what is it about the wave reflection model and the
conservation of energy principle with which you disagree?

Any rational, sane person can't believe his claims. Hopefully,
that is most of us reading some of the garbage going on in here
now.

I found it uproarious that Robeson tried to cover up his NOT naming a single military radio that was operational during his alleged 18-year "USMC career," claiming "all the information is classified!" :-)

Absolute bullshit. The names, ID, functions have all been in public view...the 'Public' being the makers or those wanting to get in on an RFQ (Request for Quote) being advertised by the DoD. Even though I never operated (as a civilian) anything more than an old ARC-27 or PRC-119 SINCGARS, all the military radios operational between the times of those two are easily recognizeable to me (well, the VRCs have lots of differences between families but the same case and general form). The operating manuals are NOT classified, just in limited distribution. LOGSA the Logistics Supply Agency is busy making CDs of all the printed manuals for darn near ALL military equipment; it's a piece of cake to pop one of those CDs in an ever-present military PC and read them. LOGSA has a website and even civilians can download some of the older equipment's manuals. LOGSA has some internal priority on what can be downloaded (depending on the cookie generated by a non-military PC). That was a tip I got from rec.radio.amateur.boatanchors and rec.radio.amateur.homebrew. The nomenclatures and quick-look facts are on a couple websites in a long, long, long list. Even BAMA has some manuals for free download plus big link lists for other sites that have them.

Robesin DID list some (questionable) nomenclatures for MARS equipment once but NOTHING else. That kind of info can be had from other hams' personal websites. MARS doesn't normally talk about regular military tactical radio gear. MARS doesn't normally use such. :-)

Reg, how about these statements from a recent QEX article?

"Contrary to popular views, the forward and reverse
waves on a transmission line are not separate fields."
"I wish to emphasize the fact that the forward and
reverse waves really do not exist separately, ..."
"Dual Directional Wattmeters", Eric von Valtier, K8LV,
QEX, May/June 2006.

The article obviously rejects the wave reflection model
for transmission lines as presented by Ramo/Whinnery,
Johnson, etc.

If forward and reverse waves do not exist separately,
how is it possible for a circulator to separate them?

>>I'd just try it, but I'm afraid it might pop in my face or something.

>Ordinary solder, no, but there are solders specifically made for aluminum.

I suspect safety guru's would say one should always wear (safety)
glasses when soldering!

It takes practice, but if you'll "puddle" some silver polish on
a spot you want to solder, rub it a bit to clean the oxide off
the aluminum, and then solder right through the puddle with a
hot iron (the stuff will bubble and sizzle, so do wear glasses!),
one CAN solder to aluminum with standard solder and without buying
some expensive stuff for a onesies/twosies job.

I don't remember how strong the solder joint was nor did I test
how long such a joint might last, but it DID solder and stick!

Cecil,

I think you are conflating models with nature, and trying to champion one correct model over another correct model! It's confusing to onlookers and boring.

There is NO inconsistency between saying "there's only one electromagnetic field in a transmission line" and "a circulator seperates the forward wave from the reflected wave" if you've suitably defined what all those terms mean and you do the correct math.

The electromagnetic field as a function of space and time in the coaxial transmission line is a three-dimensional time dependent field. There's a description wherein one single vector valued function E(r,phi,z, t) describes the electric field and another describes the magnetic field, and of course, you can get one from the other, so in some sense, all you need to describe what's going on is E(r,phi,z,t).

Now, in the coaxial TEM mode the radial and azimuthal dependence of the fields becomes trivial, and you're just left with some function E'(z,t) to describe the electric field, and one B'(z,t) for the magnetic field (once again, you can of course, get one from the other) It turns out that mathematically you can represent this function as a superposition of other functions, forward and reverse traveling waves. It's just a DIFFERENT WAY OF WRITING IT DOWN.

A circulator *doesn't know math*. Its operation may have a simple description in the language of forward and reverse waves, but it does what it does no matter what model you use to describe it. If you get different answers using a forward and reflected wave description than some other description, then one or both of your descriptions are wrong. The conversion of one mathematical description of the electromagnetic field into a series of statements in English and the argument based on those words never gets you anywhere on this topic. Why not pick up a copy of Jackson's Electrodynamics and write down what you're trying to say mathematically. If you're right, everyone will have to be convinced.

73,
Dan

Hi John,

Your comments were perfectly inoffensive to anyone. Sorry if I gave you the impression that I thought so.

I don't agree that my statement about Time and Reflections is in conflict with transmission line theory as described in the books (bibles) lining your office shelves.

We diverge because my education was probably altogether different to yours and so we don't speak the same language.

Time is represented in Phase Shift. Reflections are echos. Line Length = Distance. Propagation Velocity = Distance vs Time.

Reg.

Nope, the mainstream wave reflection model is being attacked
as incorrect.

I'm trying to correct some misconceptions concerning
violations of the conservation of energy principle
by simplified model shortcuts. Modern RF EM textbooks don't
deal with conservation of energy. There's no equations to
quote because the textbooks ignore the problem.

For instance, it can be shown that a one-second long lossless
transmission line with a measured forward power of 200 watts
and a measured reflected power of 100 watts does indeed in
reality contain 300 joules of RF energy traveling at the speed
of light. Is there really any more logical location for those
300 joules than in the forward and reflected waves which are
necessary for standing waves to exist?

Einstein said a math model of reality should be as simple as
possible but not too simple.

Source record: 53906

The fundamental partial differential equations of transmission lines
are -

- dv/dz = R + L*di/dz

- di/dz = G + C*dv/dz

where volts v and current i are incremental functions of distance and
time, and z is incremental distance along line.

Everything else follows.

Similar equations can be written in terms of frequency.

It is often easier to think in terms of Time and Distance rather than
Frequency and Impedance.

Cec,

You forgot to allow TIME into the argument.

The two waves do NOT, and cannot, exist seperately in time.

The circulator merely divides the STEADY STATE, instantaneous, at the same time, power in the wave into two parts according to what the operator, or by design, has set it to do.

When the generator is switched off both parts disappear simultaneously.

I know this won't satisfy you.

Reg.

I'm not sure what your point is. If a laser beam is
aimed at a mirror, do the forward wave and reflected
wave exist separately in time? If we send a forward
wave down a one-second lossless feedline for one second
and turn it off, nothing happens for one second. Then
we receive a reflected wave for one second. Do those
waves not exist separately in time?

> The circulator merely divides the STEADY STATE, instantaneous, at the
> same time, power in the wave into two parts according to what the
> operator, or by design, has set it to do.

The point is that one of those parts has made a round
trip to the load and back as can be proved by observing
ghosting in TV signals.

> When the generator is switched off both parts disappear
> simultaneously.

Not entirely true. The reflected wave would continue to
exist until the energy in the transmission line is
dissipated.

Thanks Jim. You're correct in every respect of course, and the cautions you've given are essentially the same as what I had already established for myself.

However, I think you'd be a little surprised (as I was) to find that there's a lack of specific guidance in the industry on these situations. At least based on my research to date.

I've found lots of anecdotal tales of arcing and sparking in these situations, but thus far nothing involving personal injury or worse. Thus far, the worst consequence I've heard of has been a plant trip. Even that is a million dollar or so event though.

I'm not asking anyone to provide input on safety procedures; just trying to pick up some ideas on what theory predicts. Maybe I should pose a purely theoretical puzzler unrelated to safety, scaffolding, or power plants.

There's a loop in a square configuration, 3 meters on a side, adjacent to a long conductor carrying 1400 amps AC at 60 Hz. The side nearest the conductor is 1 meter from it. The loop is made of aluminum tubing 75cm in diameter.

What current is induced in the loop when it is closed? What voltage exists across the gap if a gap is cut into the loop?

73--Nick, WA5BDU

BTW: 1,400 is 5% of 28,000

-> I've worked on some of those really big battery banks too.

Cecil,

I recall that you selectively quote only those parts of messages to
which you disagree. I guess you accepted the remainder of my comments.

You quite clearly said that "steady state" is not really steady. I
challenged that in a straight-forward manner. So what is "ad hominem"
about my message?

<ad-hominem>

This is a typical trick, Cecil, when you have been caught dealing
nonsense. You ignore the issue and attempt diversion. It won't work
here. The meaning of steady state is not controversial.

Cecil,

My only comment was in regard to the definition of steady state. I am not sure why you directed this list to me. I have three out of the five references you list, and I have multiple equivalents for the others.

I doubt that we have different definitions of "steady-state".
I didn't post a definition and I don't recall you posting one.

What I said was that some of the 300 joules existing in the
one second long transmission line during steady-state was
supplied by the source before steady-state was reached,
i.e. during the initial transient state.

True, I've never had much success during 2 metere aurora openings with
anything BUT CW. It ain't CW by the time it gets to the other end, but
it's still readable there.

Cecil,

Your exact words were:

***
Steady-state had a beginning and it will have an end. It cannot be
analyzed without knowing what happened in the beginning and what will
happen in the end. Steady-state is the rug under which you and others
try to sweep the laws of physics including the conservation of energy
principle. I'm doing what I can to call your bluff.
***

This says that steady state depends on something else, namely the
beginning and the end of the steady state condition. That is simply
incorrect. In steady state conditions there is no concept of beginning
or end.

<ad hominem>

If you don't know the rules, you can't play the game.

You're preaching to the choir, Dave. I've had to handle foreign
language traffic phonetically by voice and by CW - and I much prefer
CW for that kind of work, even though I prefer voice for most
rag-chewing. As you say, needing it spelled out is quite slow.

They don't get it wrong - they just don't discuss it at all.
But here is an example of the problem:

http://eznec.com/misc/food_for_thought/

First article - last paragraph. W7EL considers
steady-state conditions while ignoring the previous
transient state conditions. He implies that the
energy in the reflected wave cannot be recovered but
it is indeed dissipated as power in the system after
power is removed from the source. The source supplies
exactly the amount of energy during the transient power
up conditions needed to support the forward and reflected
waves during steady-state. This is easy to prove. But
W7EL's Ivory Tower protects Him from peons like me.

A 12VDC battery is sitting there with a 200 amp*hour charge. Are
you asserting that there is no concept of where the 200 amp*hours
came from? Please tell me you are not that stupid.

Consider the one second long transmission line with 200W of forward
power and 100W of reflected power. That requires 300 joules of
energy during steady-state. If the 300 joules was not supplied
during the transient state, then it must have magically appeared
out of thin air in violation of the conservation of energy principle?
Is that what you are trying to tell us?

I prefer phonetics myself. So are you advocating using the
coercive force of the federal government to enforce your
preferences instead of mine? Of course you are!

Thanks for the feedback on the 6m elements and the 4 ele SteppIR. I want to go for the 3 ele. because the boom length is the same as my existing beam. I could (just about) fit a MonstIR into the yard, but I don't want to get a beam antenna that big. My neighbours have come to terms with the metal monster, as-is. If it got even bigger, I think I would have a bit of problem with them. I can always change it to the 4 element then the MonstIR and they would hav it 'grow' on them.

My current beam has a rotatable dipole on 40. For me it is just neater and more convenient than having an inverted-Vee.

Big advantage for me with the SteppIR is that it is mostly fibreglass tubing so corrosion will be less of an issue.

40m through to 6m with one feeder! Luverly!

The net power flux in the line gets smaller as the reflected wave gets stronger while maintaining a constant electric field (constant voltage as in Roy's example). If you can match to the new impedance at the line input; that is, make the electric fields both stronger, you can get a larger net power flux even in the presence of some elevated SWR.

See LaTeX formatted math at
http://en.wikipedia.org/wiki/User:Dan_Zimmerman/Sandbox

The flux of stored power in the line, interestingly enough, is a sinusoidal function of position.

I'm still thinking what to make of it, but I thought I'd post the math for people to look at (and check, please!!!!)

... I'll be back later.

I attended 3 weeks of CWPC training at Maxwell AFB in Montgomery,
Alabama. It hosts CAP HQ. Didn't see any CAP uniforms there, either.

Odd, though. The new owner of robesin's old vanity callsign, K4CAP,
resides in Montgomery, Alabama.

Source record: 53838

Greetings,
A soldered joint to aluminium won't last. For a good
electrical connection to aluminium get some jointing compound
suitable for ensuring an electrical contact between dissimilar
metals without corrosion. One has to use the same stuff for
aluminium to aluminium connections as well or the aluminium will
oxidise at the joint. Required for long (HF) yagi elements.
Put the jointing compound on the cleaned aluminium and on
the wire then fasten them together; by clamp, screw whatever.
Some would tape up the joint so the jointing compound doesn't
blow or wash away.
There's an article in Radcom July 2005, p75 Technical topics, on
working with aluminium.
I've assisted engineers/technicians constructing/repairing HF
yagi's on which every single aluminium to anything connection
that has to conduct has the compound put on. Note that copper
corrodes aluminium and that tightly clamping aluminum is
useless at stopping oxidation in the joint. Take the joint
apart later and everything will be wet ...
Good luck.

Hi Nick

Are actually able to get anywhere close to a 1,000 megawatt 3 phase power
line without strict supervision from the management of that station??
My limited experience with stations associated with that voltage and
curent indicate that there are really well qualified electrical engineers
close by at all times. They have always seemed capable of understanding
inductive coupling and have maintained close supervision of all personel
near the plant.
Where is this location?

Cecil,

You can wave your hands all you want, but it won't have much impact on the correct math and physics.

Try writing the appropriate equations for your puzzler, in steady state conditions, and then figure out where to insert the transient behavior. Good luck.

This is basic stuff taught in numerous math and technical courses. If don't accept the basic math, then I guess we will not agree.

73,
Gene

> Try writing the appropriate equations for your puzzler, in steady state
> conditions, and then figure out where to insert the transient behavior.

I have already provided the equations, Gene. In a one second long
lossless transmission line, 200 watts of forward power equals 200
joules of energy in the forward wave. 100 watts of reflected power
equals 100 joules in the reflected wave. Total joules in the
transmission line equals 200 + 100 = 300 joules. The equations
are trivial.

> I'm still thinking what to make of it, but I thought I'd post the math
> for people to look at (and check, please!!!!)

Thanks, Dan.

If I understand correctly, Roy's argument is that since
the source is not supplying any steady-state energy to
the lossless stub, there is no energy in the reflected
wave within the stub.

If we make Roy's lossless stub one second long, the
picture becomes clearer. For the first two seconds,
the 100 watt source pours 200 joules of RF energy
into the stub. After that, during steady-state, the
source supplies zero energy. But those 200 joules
are still in the stub, 100 joules in the forward
wave and 100 joules in the reflected wave, and they must
obey the conservation of energy principle.

There is *always* the exact amount of energy in the
forward and reflected waves as required to achieve
the forward and reflected power readings in a Z0
calibrated environment.

Hi Gene,

The bare contradiction is enough to condemn this thread.

However, it does have its amusing character of "Who's on first?"

Continuing that metaphor, Cecil would believe having been born on
third base, that he had hit a triple to be there. ;-)

For the concept challenged,

Being on third is the steady state.

The transient state is one of:
Being born;
hitting a triple;
hitting a double and then a batter advancing the runner(s);
hitting a single (then like wise with the batter's assist);
stealing a base;
or two.

The steady state also has to satisify other conditions that were taken
up by transients like outs and innings. e.g. being on third with
three outs does not mean you can stay on third.

Thus the next transient is
The side is retired (state change)
or, as in this case of the bottom of the ninth and an untied score
The game is over (solution).

Every antenna I ever bolted to a mast twisted. Tri-banders, 2M, TV antennas always land up pointing in the wrong direction. I've had antennas actually rotate, winding the coax around the mast till it pulls off. Does anyone have a tip for keeping antennas fixed to the mast? No matter how tight the U bolts are, the wind aways seems to win in the end.

Not me. MY federal government dropped the code requirement a while back--and with my blessing. The sky didn't fall (at least not any further than it already had). But having used CW professionally for years, I know both its strengths and its weaknesses. Its main weakness is that not everyone can do it. PSK31 and PACTOR get a bit of an edge on it when there is no large ionospheric phase distortion happening, but require significantly more equipment.

Back in 1976 when I was doing weather observing for a living on Sable Island, we were required to send the results of two balloon soundings and hourly surface observations to Halifax by RTTY. At night that 2mhz RTTY circuit often became impossible. Nor was the AM circuit any good. I frequently got out a key and sent it on CW. It was actually funny when one of the department's high mucky-muck techs came out to the island to fix the problem. I pointed out that verticals were great on 2mhz for a 192 mile path in the daytime but that they got bogged down in DX signals and QRN at night and suggested that he could improve things by giving us dipoles at both ends for night use. I also suggested that a properly designed VHF link would be superior. He laughed at me. Funny thing is, that man's son went out to Sable afterwards and installed a beacon that I could ALWAYS hear in Halifax, running 8 watts on 144mhz.

The thing is, you don't always know what is saving a life. Those weather observations may have made no difference to anything or they may have made a huge difference to how someone flew a 747.

I don't bother with low-IQ clubs myself. Or high-IQ ones for that matter.

I did do some work on the question of human intelligence back in the 60's.
It was interesting. We used factor analysis (now called PCA) and came to
the conclusion that it is a six-dimensional vector quantity--to the extent
you can measure it at all.

A correction - insert dt instead of dz.

The fundamental partial differential equations of transmission lines
are -

- dv/dz = R + L*di/dt

- di/dz = G + C*dv/dt

where volts v and current i are incremental functions of distance and
time, and z is incremental distance along line.

Everything else follows.

Similar equations can be written in terms of frequency.

It is often easier to think in terms of Time and Distance rather than
Frequency and Impedance.

Reg.

For several antennas I am using an add-on to the u-bolt. See it (or
similar) used with a u-bolt as item 8718 on this page:
http://www.teeveesupply.com/product_pages/antennas/antenna_mounting_hardware
.htm

The toothed edges seem to dig into the mast section enough to keep it from
turning. If you need to be really secure, I suppose you could pin it
through the mast. The pinning idea also works with the antenna alone, but
I'd avoid putting another hole in the boom. Also, a pin alone allows some
angular movement, which you are setting out to prevent.

You may need a longer u-bolt than came with the antenna.

That sounds right... if the reflection coefficient is 1 then there's no net power flux into/through the line in steady state, and this can be described if you like by counterpropagating waves each carrying the same amount of energy.

The problem is, in your other example where you say 200 joules in the forward wave + 100 joules in the reflected wave = 300 joules in the line total, you're neglecting the vector character of the power flux.

Yes, the waves carry energy, but they carry it in different directions. The net power flux in the line with 200W forward power and 100W reflected power is 100W net power flowing to the load from the source. The real part of the Poynting vector of the reflected wave opposes that of the forward wave, as long as I got all the signs right.

I don't think we can neglect the imaginary part of the Poynting vector, though. It's not zero and I think it represents the flow of the power in the stored fields in the line, and if we want to get the total energy in the line, we have to include the stored fields.

As long as gravity exists will it ever be possible to get a perfectly horizontal dipole? In spite of a strong tensile component there will always be a vertical component due to gravity (with a centre feed there will also be the weight of any cable and perhaps a balun as well). The net effect is a sag called a catenary. Granted an infinite tension on the antenna wire would probably overcome the vertical component but the wire might not survive. The question for this relative neophyte is, what effect does the sag have on antenna performance?

Most likely less effect than nearby objects like houses, trees, earth, moon,
sun, and rain. :-)

"How many pins can be placed on the head of an angel?" makes more sense than
hypothesizing about the effect of catenary on wire antennas.

That is actually the other side of the argument. When
an observer arrived after the game started, Cecil was
on third base. Using steady-state logic, the newcomer
assumes that Cecil is there without ever having to swing
a bat.

Someone looks at a transmission line during steady-state.
The source is supplying 100 watts. The load is dissipating
100 watts. The forward power is 200 watts. The reflected
power is 100 watts. The incorrect assumption is that the
source is incapable of delivering the 200 watts of forward
power and the 100 watts of reflected power. But the exact
amount of energy required to support those values
was provided to the transmission line before steady-
state was reached. It was rejected by the load and is
still there in the transmission line during steady-state.

If the counterpropagating waves each carry the same amount
of energy then there cannot be zero energy in the reflected
wave.

Some people on this newsgroup say that the wave reflection
model is invalid, that forward and reflected waves don't
have a separate existence. From QEX: "Contrary to popular
views, the forward and reverse waves on a transmission line
are not separate fields." It would follow that a laser beam
normally incident upon an ideal mirror results in a beam of
light not superposed from separate forward and reverse fields.

I have challenged people holding those concepts to create a
standing wave without superposing separate forward and
reverse waves and have gotten zero responses.

> The problem is, in your other example where you say 200 joules in the

I apologize if I accidentally gave that wrong impression.
I subscribe to Ramo/Whinnery's notion that the power reflection
coefficient is equal to the reflected Poynting vector divided by
the forward Poynting vector. Pz-/Pz+ = |rho|^2

> Yes, the waves carry energy, but they carry it in different directions.

> of the forward wave, as long as I got all the signs right.

Yes, that's what I am saying. The other side would assert that
there is no reflected Poynting vector and no forward Poynting

vector - that there only exists the net Poynting vector. This is a change away from mainstream RF engineering taught in the 1950's. The "modern" concept seems to be that forward and reflected waves don't exist. All that exists are the standing wave and the net forward traveling wave with nothing moving backwards.

Cecil,

You've set up a false dichotomy here. When I, and others, write "The electric field is the superposition of a forward and reverse traveling wave" maybe it would be better to say "The electric field has two terms, one that appears to be a forward traveling wave and one that appears to be a reverse traveling wave." or something like that. There's one electric field vector and one Poynting vector. Or there are two. The structure of the electric field and the structure of the real part of the Poynting vector both admit BOTH explanations of what's happening.

You're not gonna get 300J in your one second line.... the stored energy flux in the line depends on the wavelength of the incident RF, and in retrospect, you might expect this from the fact that a misterminated line goes through cyclical impedance variations as you change its length (something that I know you're quite familiar with :-))

I think the energy density per unit length in the line is proportional to the Poynting vector (or it's integral over the cable cross section, and the proportionality constant is the group velocity of the waves, I think) I left Jackson at work, so I'm not certain right now. What I am certain of is that you can't take the energy in the forward wave and add it to the energy of the reflected wave and get that there are 300J in a 1 second line carrying a 200W forward wave and a 100W reverse wave. Rather, there's a 100W net forward power flux and THAT will give you the energy contained in the part of the field that's actually moving from source to load. The energy contained in the reactive part has an integral that's going to cyclically vary with the length of the line, and sometimes goes through zero (kL or kL - phi equal to an integer multiple of Pi... or any integer multiple of a half wavelength, which happens to be the length of an impedance repeating line, eh?)

Dan

The "newcomer" must be defined in the IEEE dictionary as "dolt" given there are many possible solutions, and only a dolt (obviously not a fan) would come to only ONE conclusion and that one being the least likely in baseball experience.

The fan sitting next to him, hearing this exclamation is undoubtedly squirming in his seat. That dolt has left unexpressed how, without swinging a bat, that the runner was advanced to third, or worse, that he got there on the basis of not swinging a bat alone - clearly a violation of laws of baseball.

Let's consider another conundrum. The dolt, having arrived late, now perceives:
1. the returned, fielded ball held by the catcher standing on home;
2. three bases loaded with runners;
3. a runner on the base line;
4. the scoreboard reveals this is the bottom of the ninth with two outs.

Are there 4 men in the transmission line, or only three with the mismatched termination at the load of home base?

The dolt would tell the fan next to him four (using specious math); the fan would say none (using the laws of baseball). Solution = the umpire would agree with the fan - and the side retires, the game is over.

In the transient end-of-state, it takes a few minutes before the dolt realizes
1. the solution;
2. he has no beer;
3. there are 75000 fans in the exits between him and his car;
4. Luigi is going to be waiting for him to cover his lost sucker bet;
5. he has no beer.

Hi

I have had to short term rent a small house, there is a covenant on the property, not to allow outside antenna's, my beam etc is out of the question. I have a full size 5RV that I am happy to butcher if necessary, any ideas how I can use this perhaps for 20 or 10. I don't want any major work done as I should be moving again in the spring, I have very little here, just a soldering iron and a few PL's everything is in storage.

Any quick idea's would be gratefully received.

wrote:

>As long as gravity exists will it ever be possible to get a perfectly
>horizontal dipole?

Hi Paul,

If you read my further responses to Owen, you find the discussion of
catenaries. In that regard, the answer to your question is
unquestionably YES!

You merely need to provide a catenary supporting the perfectly
horizontal dipole. Regard any suspension bridge to discover the
mechanics of construction. And, yes, the road bed is not horizontal,
but an arc built to anticipate load; the ingenious antenna builder can
reconcile this (trolley systems across the world with overhead
suspended wires solve this easily).

> The question for this relative neophyte is,
>what effect does the sag have on antenna performance?

Barring the suspension method, and the wire sags, it becomes a
question of how much, and more importantly, in what relation to
ground? If you have a 160M dipole with the ends up 10 meters, and a
sag of only 0.1ï¿½, then you still have a dog. If it is a 10M dipole
with a 10ï¿½ sag, then you have a performer. This is a 100 fold
variation that would seem to invert expectations - if were not for the
wavelength and relation to ground.

Why not just string a loop around the top of the highest room in the house,
and feed it with a tuner. In the past I had pretty good results with
this...not as good as a full sized outdoor antenna, but cheap and easy to
install.

Cecil,

I believe Dan has addressed this issue, and I am sure that I have on
many occasions.

When superposition applies, as it does in this linear, non-pathological
case, there is no difference between the reality of the components vs.
the reality of the sum. In other words, there is no more information
from your separation of a standing wave into forward and reverse
components than there is in the standing wave itself.

The standing wave is a perfectly good and complete solution to the wave
equations applicable to this steady-state problem. It is possible to
sub-divide in many ways, but there is no new information in doing so.

If you want to specifically address transients then another set of
equations will be needed.

<ad hominem>

You have railed against seduction by math models on many occasions.
However, that is exactly what you are doing here. Trying to create some
new physical reality by manipulating the numbers.

I know and accept both explanations. The problem is the other side
refuses to acknowledge the validity of the wave reflection model.
If you have gotten the idea that I reject the superposed wave model,
you are mistaken. I fully accept both models. The problem is that
others have rejected the non-superposed component wave model.

I contend that one gets the same results using the components of
superposition, i.e. the forward wave and the reflected wave, that
one obtains after the superposition of those two waves. Others say
that is an invalid treatment because superposition causes the
reflected wave to cease to exist and the energy just "sloshes"
around inside the transmission line. (Never mind that RF energy
must necessarily travel at the speed of light and only reverses
direction at an impedance discontinuity.)

> Rather, there's a 100W net forward power flux and THAT will give

> has an integral that's going to cyclically vary with the length of the
> line, and sometimes goes through zero (kL or kL - phi equal to an
> integer multiple of Pi... or any integer multiple of a half wavelength,
> which happens to be the length of an impedance repeating line, eh?)

That's one model. The other model is, assuming a purely resistive Z0,
the forward voltage is in phase with the forward current and therefore
there are no reactive vars in the forward wave. The reflected voltage
is in phase with the reflected current and therefore there are no
reactive vars in the reflected wave. This model works just as well as
the one above, sometimes better because of simplicity. It has the
advantage of being easily able to track the real energy because there
is no "unreal" energy in the model. :-)

If the forward wave component is analyzed separately, there are no vars
because the forward voltage is in zero phase with the forward current
(assuming a perfectly resistive Z0). The same is true for the reflected

wave. So we are easily able to calculate how much energy is contained in those two waves devoid of any calculation of vars.

Assume that we have a one megahertz signal into a transmission line that is electrically 360 degrees long, near lossless, the forward power is 200W, and the reflected power is 100W. I am willing to bet the energy contained in the feedline during steady-state is very close to 300 microjoules no matter how complicated the math used to get the answer that I just came up with off the top of my head.

Note that the transmission line is one millionth of a second long and therefore contains one millionth of the energy of a one second long line.

One can also use more than one room. It might give a
strange shaped loop but it allows adding more wire
until resonance is achieved on the lowest frequency
of interest. I once used 2 rooms and a hall for my
2nd story loop.

```
+--------+ +--------+
| | | |
| | | |
FP +---------------+ |
| |
+---------------------------------+
```

How's that for a loop? Fractal?

I say it's 100 microjoules.

200W forward - 100W reverse = 100W net forward power. The percieved issue of some people not believing in the seperate forward and reflected waves just doesn't come in here... it's that the real part of the Poynting vector is REDUCED by reflections. If you want to contest this point then you need to tell me where the sign error is.

If you have a constant voltage (constant electric field) output on your radio then this effect actually causes LOSS of power transfer through even a lossless line.

You've got a 200W matched condition, power flux is 200W. You have 100W reflected wave, you get a net power flux of 200W - 100W = 100W. You can see this from the Poynting vector which is proportional to the difference of the squares of the electric field amplitudes of the forward and reflected waves. You can also do this with lumped circut impedance analysis too.

If you can't bump Ef up by using an impedance matching network, the net power flux is REDUCED by the reflected wave, and as such, the stored energy in the fields in the line is ALSO reduced. If you can increase the forward electric field in the face of mismatch, you can push the 200W into the load.

The reflected wave makes it so you need more voltage to push RF down the coax.

Not 300 microjoules. 100 microjoules. The energy per unit length in the line is proportional to the Poynting vector.

Dan

I accept both methods of analysis. What I object to is people
rejecting the wave reflection model. e.g. "Reflected waves
don't really exist and don't really contain any energy."
As in the earlier discussion about standing wave phase, you
and I wind up on the same side of the argument.

What I object to is the irrational conclusions drawn by proponents
of the standing wave analysis. Here are some of the past assertions:

Forward waves and reflected waves cease to exist after they have
been superposed. The standing wave is all that is left.

Question: If the components of superposition cease to exist,
doesn't that mean the products of superposition also cease to
exist? (No answer)

Standing waves don't require a forward wave and a reflected wave.

Question: How does one obtain a standing wave without a forward
traveling wave and a reverse traveling wave? (No answer)

> You have railed against seduction by math models on many occasions.

I have railed against the assertions that superposition destroys
forward and reflected waves such that they cease to exist in reality.
From a recent QEX article: "I wish to emphasize the fact that the
forward and reverse waves really do not exist separately, ..."

So I ask you, Gene, if forward waves and reverse waves do not
exist separately, how can they possibly be superposed? Seems to me,
the above statement from QEX is a violation of cause and effect.

If forward waves and reverse waves do not exist separately, how
can they possibly be separated by a circulator?

> I say it's 100 microjoules.
> 200W forward - 100W reverse = 100W net forward power.

Sorry Dan, you are right about the power and wrong about the energy. There are indeed 100 watts of *net* power. But we are not talking about the net energy delivered to the load. We are talking about the total energy in the transmission line and there's no such thing (to the best of my knowledge) as negative energy. Forward traveling energy is positive energy. Reverse traveling energy is positive energy. The energy rejected by the load is NOT negative energy. Forward traveling energy and reverse traveling energy add, not subtract.

Hint: Two energy components cannot superpose to a zero scalar value. The result is always a scalar sum.

If we have 200 microjoules in the forward wave and we have 100 microjoules in the reflected wave, the total energy in the transmission line is 300 microjoules. If the standing wave model differs from that amount, it is wrong.

> You
> can see this from the Poynting vector which is proportional to the
> difference of the squares of the electric field amplitudes of the
> forward and reflected waves.

True for net watts, not true for joules. In the standing wave model, there's 100 watts of net power containing 100 microjoules. The other 200 microjoules are stored in the (virtual) reactances. If you calculate the energy necessarily stored in the L and C of the line, you will find the other 200 microjoules. I would have to hit the books to refresh my memory on that calculation but any other result would violate the conservation of energy principle.

> If you can't bump Ef up by using an impedance matching network, the net
> power flux is REDUCED by the reflected wave, and as such, the stored
> energy in the fields in the line is ALSO reduced.

That applies to the watts. It doesn't apply to the vars. The actual voltages and currents are increased by the standing waves while the phase angle goes non-zero. Vars require real energy. That real energy can be calculated by knowing the current through a perfect inductor and/or the voltage across a real capacitor.

> Not 300 microjoules. 100 microjoules. The energy per unit length in
> the line is proportional to the Poynting vector.

The energy per unit length is not proportional to the net Poynting vector which is (Pz+ - Pz-) (using Ramo/Whinnery conventions). The energy per unit length is actually (Pz+ + Pz-). Why that has to be true is contained in the conservation of energy principle and is the source of confusion for many posters on this newsgroup.

Hint: Has anyone ever seen a quart of negative water?

thanks for the info but Heil Sound does'nt even show this unit on their
website.

I would think if it really works would'nt HS still have it on the website?

I bought my two before Heil took them over. I suspect Heil
priced the devices too high to be economically viable.
I would recommend as an alternate - buying a used device.
They really do work well.

Clearspeech units do NOT keep noise OUT of the first RF stage. They operate as audio DSP. It is a totally different approach from either the ANC-4 and the MFJ 1025.

I own both the ANC-4 and the MFJ-1025.

These units use a separate noise sensing antenna mounted close to ground. Mine are about 20 feet long and about 3 inches above the ground.

Both units use analog operational amplifiers to cancel manmade noise BEFORE the noise enters the receiver [before the first rf amplifier stage].

Operation is easier to describe in terms of two op-amps. Op-amp#1 adjusts the gain of the input#1 noise to match the noise level and inverts the noise signal. [-mmnoise#1 @ input#1]

Op-amp#2 has one input from the station antenna that contains signal plus manmade noise [signal + mmnoise] and the second input from the noise amplifier [-mmnoise#1] that has inverted noise only. This amplifier algebraically adds the two signals [eg: signal + mmnoise - mmnoise]. The output of this amplifier has just signal. The manmade noise has been canceled!!

In my station the ANC-4 is used primarily because it is simpler to use. There are only two adjustments, noise gain and noise phase.

The MFJ-1025 has three adjustments, noise gain, noise phase and T/R delay [for QSK type usage]. I don't use QSK so I can't comment on this feature.

Each unit has several push buttons for basic frequency range.

Both units will easily reduce manmade noise, power line noise, switching power supply noise, noisy power insulators, Computer monitor noise, tv set noise, etc by 60 to 70 dB. A S9 noise level can be reduced to less than S1 approaching S0. Both units have a slight reduction in net RF gain of about 1/2 S unit. Either unit will allow you to copy a S1 signal in the presence of S8 or S9 external manmade noise [NOT adjacent channel QRM!!][They are VERY broadband noise amplifiers].

The ANC is physically smaller and has two adjustment and two push switches. The MFJ has three adjustments. I have not opened the case of either unit so I can't comment on construction quality.

I bought my MFJ new from HRO. I bought my ANC off eBay. Why two noise cancellers? I have two HF rigs operating simultaneously in my shack.

The ANC is my favorite because of ease of operation. It is on my IC-756 Pro III [basic HF rig]. The MFJ-1025 is on my 60 meter dedicated radio.

3060. Impedance of small delta loop

Newsgroup: rec.radio.amateur.antenna
Date: 2006-08-26 21:25:40 UTC
From: Andrew Holme <andrew@nospam.com>
Message-ID: <ecqe8egkg1$830fa7a5@news.demon.co.uk>
Source record: 53796

I've erected a delta loop in my back garden for general shortwave listening, with a total wire length of 75 feet, fed with 75-ohm coax via a balun. The balun is a 3:1 turns ratio transformer wound on a small red toroid from my junk box. The winding on the coax side is about 20uH, and the winding on the loop side is about 200uH. I've no idea how close to, or far from optimal this is. I mostly listen to hams on 40 and 80-metres. I've no idea what the impedance of my loop is on these bands. It would be useless for transmitting, because it's less than one wavelength, but it seems to work OK on receive. The noise level is certainly nice and low. My questions is: what is the impedance likely to be on 40 and 80-metres?

TIA
Andrew.

More info: the feedpoint is at the centre of the base of the delta, the apex
is supported from a chimney, and the other two corners are about 8 feet
above ground, guyed off my back fence. The plane of the delta slopes.

Great idea....I wish I had thought of that at the time. The biggest loop I
could get in the attic was for 15m, and it worked pretty well on 10 and 15.
On 20 it was suffering, but still useable. The one downside was that RF got
into my solid state heat/air control box and burned it up. A toroid over
the input wiring solved the problem.

You won't find exactly what I am saying in Ramo/Whinnery.
I'm pre-assuming that you accept the conservation of energy
principle. :-)

My 1950's Texas A&M college textbook was, "Fields and Waves
in Modern Radio", by Ramo/Whinnery, 2nd edition pp 284-296.

wrote:

>wire might not survive. The question for this relative neophyte is,
>what effect does the sag have on antenna performance?

Yes, perhaps you got on the wrong tram in the discussion about sag. It
would be easy if you hadn't read the entire thread.

Low sag is obtained by high wire tension.

High wire tension under static conditions increases the risk of
breaking under wind loading.

Antennas that have broken don't perform so well.

Owen

PS: In answer to your question as to whether a dipole can ever be
perfectly horizontal, perhaps no, perfect is probably not achievable
by any real thing, but yes, it can be done to a close approximation,
but it is probably not practical in most situations. Think of an
electric railway with overhead power, the power conductor is very
close to constant grade and parallel to the tracks, think of
suspension bridges with an approximately flat roadway. There are of
course other solutions as well.

Hi Andrew,

Your antenna's Z in the 40M band is astronomical:
Impedance = 12740 + J 8376 ohms
in the 80M band
Impedance = 98.29 + J 1069 ohms

Skip the lore about baluns (which you couldn't possibly hope to
find/build/buy), what you need is a tuner and second smaller loop
(think half the size) in parallel with the big one (to pull down that
astronomical mismatch).

73's
Richard Clark, KB7QHC

you use an antenna thats 20 ft long would that be a dipole?
3 inches off the ground?? no kidding, any idea why so low?
what kind of wire do you use to connect the noise unit to the antenna?

would you say the units eliminate the noise equally as well?
or does one seem to be better than the other?

Yeah, me thinks you're right. This thing has dragged on long enough. It is getting boring. What IS - IS and until someone - like the FCC changes things - it shall stay as it is. No amount of bitching here will get it done. So, if you want a license, lump it and learn it. If not - its your loss.

With such a high VSWR the loss on 100 ft of 450 ohm ladder
line is only about 1.1 dB on 7 MHz. Typical tuner loss about
0.5 dB.

Hi,

I just got a used Butternut HF6V in great shape for a great price. What type of anti-sieze do I need to put between the sections of aluminum tubing ??? Is automotive anti-sieze OK ??? I don't think that it is electrically conductive. Do I need something like electricians use when they connect the aluminum service entrance cable to the breaker box ??? I think that stuff is called Penetrox. Is something like that available at Home Depot ???

>
> Dan
>

Superior is a judgement call, and if you like it better, than it's superior for you. For myself, I prefer having the insulation on the THHN wire I use, as I can't always keep the wire "in the clear". Also, one of the reasons I gave up on copperweld was it's stiffnes and propensity to kink, making a weak point that invariably failed in relatively short time.

Of course, living in an area with significant acid rain (living on the side of a volcano does have some drawbacks), it doesn't take much of an abrasion to compromise the copper coating on copperweld, and once that happens, rust soon follows, and down comes the antenna. (The PH of our rain here is around 3.5... Neutral is about PH 7 or 7.5. Just about anything that can will either rust or corrode here. Even tools in a closed cabinet will rust if you don't take them out and oil them fairly often, something nearly unheard of in most of the US.

Whatever you use, the main goal is to get wire in the air and keep it there, so you can talk to the world. Whatever methond you use is up to personal preference, and that's one of the things that makes this hobby interesting.

Good Luck!

You've insisted on posting this crap so many times just about anyone with more than two or three brain cells would be sick of it by now. Why don't you just crawl back under the rock you crawled out from under?

At this point, even a relative moron should get the point that there are a bunch of people that really don't give a damn about CW. That you do is not the point, but your continual posts about it are the point. Therefore, your continual posts lead me to believe you should be seeking mental help. If you don't think you need therapy, how about you get a life and if you are so Pro-CW, why aren't you on the bands right now?

Though I'm an Extra and passed the CW requirements shouldn't make a difference if I choose to operate phone. If the requirements change and new Hams aren't required to take the code test, am I going to be pissed? Hell no, because I took the tests when I did because I wanted to be a productive part of this hobby, not wait for an easier ticket in. I learned it, just as a huge number of others have, but none of us wish to push it like you seem to want to. Even the most die-hard CW fanatic is spending his time on the bands, not on the internet trolling for arguments.

Now, to provide a response to your query: It is extremely unlikely that with all the means we have for contact in the case of an emergency, that CW would be the only way to make contact, particularly if you live in anything near an urban evironment in mainland US. First and foremost, there has to be someone else that will respond to you, and given the things going on with the hobby lately, I doubt that CW will be the safety net you'd like to believe it is.

For myself, I have HF and VHF in both the house and vehicle, and have the VHF radios all programmed with all of the local police and fire frequencies. In a true emergency, I wouldn't lose a moment's time worrying about whether it was legal or not before I keyed up on a public service/fire/police frequency if it meant saving somebody. Would CW help? Not very damn likely, as first I'd have to key up the HF rig, get to someone that could relay, pass a message, hope like hell that they actually did call the proper authority, (and were believed), and so on. You can bet I'll get attention right away if I key up on any of the public service frequencies, and they damn well will respond, if for no other reason than to find me. If that's what it takes, so be it, they can fight it out in court later, and I'd get so much media attention they wouldn't dare push it very far. On the other hand, the likelihood of actually being believed using standard, HF and CW procedures, or getting help in a timely manner to actually save a life is an extremely remote chance...

I rarely filter anyone, but you've definitely earned the "plonk" of
being filtered. Say Bye-Bye ! ! !

--Rick AH7H

Rick...point well made, tho a bit wordy.
I happen to be in a position whereby I work in law enforcement and have more that one HT in the home charger, said HTs being on the local PD freqs.
Save a life? CW? Not hardly! That is a moot argument, one with no merit save for the spammers who wish to continue the thread for their own, selfish entertainment.
In an emergency I use one of the HTs. They work even when the cell phone service is out.
In a true emergency, CW is not fast enough. It is archaic. It simply doesn't cut the proverbial mustard.
Keep a Marine battery on hand and keep it charged. One can work any number of radios from that.

'Nuff said.

3091. Graphical NEC2 application for Linux

Newsgroup: rec.radio.amateur.antenna
Date: 2006-08-27 08:34:45 UTC
From: neok <n5b4az@yahoo.com>
Message-ID: <1156667685.445635.296240@75g2000cwc.googlegroups.com>
Source record: 53727

Hi All,

I just uploaded a new beta release of xnec2c, a graphical (GUI) application which incorporates nec2c, my translation to C of NEC2, into an interactive antenna analysis and visualization tool. xnec2c does not need and does not produce a NEC2 output file (unless requested) to visualize results like radiation patterns or frequency-dependent data. Instead, results produced by the incorporated NEC2 engine are stored in buffers and presented in graphical form as they are produced in the frequency loop (watch the max gain and VSWR plots grow before your eyes! ;-)). All frequency dependent parameters that are displayed (including radiation patterns) can be re-calculated for a new frequency by either clicking on the graph of frequency-dependent data or entering the frequency in a spin-button widget.

xnec2c now incorporates a basic NEC2 input file Editor that simplifies the creation and editing of NEC2 input files and speeds up the edit/save/reload cycle. This editor also hides most of the awkward details of the NEC2 input file and so reduces the need for detailed knowledge of this file's format.

This is a fresh beta release of xnec2c and likely to have some bugs/annoyances but it was hard for me to code since I am under heavy pressure from illness in the family. However I will try to find time to fix new bugs, hoping xnec2c will become a useful graphical NEC2 derivative for Linux users.

Look for xnec2c (and other ham radio apps) in my website:
http://5b4az.mattsnetwork.co.uk/

==========

What type of helix do you want?

End-fire or broadside radiation pattern?

They are altogether different in construction.

The 20 feet long antenna is exclusively a NOISE SENSING antenna. It is used for the NOISE channel on the ANC-4/MFJ-1025. It is simply a wire plugged into the back of the units.

Mounting it close to ground minimizes the HF/RF signals while picking up the manmade noise [mmnoise from my previous post] signals.

The ANC-4 works very well with the short NOISE Sensing antenna. The MFJ-1025 works better IF the NOISE SENSING antenna is longer and higher [like a second HF antenna]. The MFJ states that it can be used to eliminate adjacent channel interference. I have never used it in this mode. [My ICOMS have an excellent ANF feature and DSP]

The ANC is very easy to use [two independent adjustments]. The MFJ takes a little learning to use [three interdependent adjustments]. Both do work!

If I had to choose one ... the ANC-4 ... ease of use and less noise antenna requirements.

I do happen to know the morse code. At one time I could do 30 wpm.

But the chance that I shall see, in my lifetime, someone drowning in a river when I have with me a battery-operated transmitter, a receiver, an antenna, ground spike, and a morse key is about one in 10,000,000,000.

I would be far more likely to plug in the microphone.

In any case, by the time I had got the gear fixed up and made a suitable contact, the poor victim could have floated out into the Atlantic Ocean.

It would be a good idea to dump the equipment and run downstream along the river bank to the nearest safety belt.

Reg.

I've come around to that conservation of energy stuff ;-)

I understand that your argument involves the energy that enters the line before it knows anything about the load, the energy that enters in an initial transient, but unless you can show that nothing happens during the initial transient to deliver some or all of that initial energy to the load, your argument has a hole.

You're presupposing that there is some energy that enters the line during an initial transient that cannot leave until you shut the source off, so you get the 100J related to the 100W net power flow and 100J that went into the line before the source knew about the load.. and then there's another 100J that enters somehow? I guess to set up the reflected wave?

The argument is circular. The initial transient supplies 200J of stored energy to the line so there must be 300J in a one second line if there's 100J in the steady-state fields associated with power flow. Since there's 300J in the line, the initial transient must have supplied 200J in stored energy. It's just not working for me.

Dan

thanks for all the info Dave.
looks like the ANC-4 is the way to go. I have downloaded the manual for
both. the noise sensing antenna that you use is it in a dipole
configuration or like a long wire?
what kind of wire do you use to go between the ANC-4 and the noise antenna?

3110. More 9m Monopole

Newsgroup: rec.radio.amateur.antenna
Date: 2006-08-27 17:12:50 UTC
From: Frank's <frank599@nospam.telus.net>
Message-ID: <moklg.17654$365.9204@edtnps89>
Source record: 53746

Reg, I think I now have a more accurate working program.
I am computing the E and H fields at only 20m, which
produces dramatically different results. Using
the Poynting Vector, S = 1/2*Re(E X H*), where
"X" is the vector cross product (H* is the complex conjugate
of H). Integrating |S| over a hemispherical region, of radius
20 m, shows a radiation efficiency of 80.3%, and a radiation
resistance of 27.7 ohms.

I have moved the test frequency to 8.1 MHz where the input
impedance of the antenna (99 x 10 m radials) is:
34.523 +j0.18. This implies a radial input impedance of
6.823 + j 0.18 ohms. These results appear to be much closer
to your program. Of course, now I am starting to wonder
if I should not redo the computation at 10 m to see how
significant the ground wave losses are. Closer than 10 m
is probably not practical since I do not think NEC can
compute the near fields in cylindrical coordinates.

The results also verify your comments concerning the
contribution of the ground wave to the total radiated
power. The "Sky wave" radiated power represents
only about 35% of the total input power.

My new Excel spread sheet contains over 4,000 active
cells, but is much easier to use than the previous method.
Using rotational symmetry, and other methods, the
NEC run time has been dramatically reduced.
I have also used almost lossless wire of conductivity
1E12 S/m. Perfect wire crashes NEC when using
the "Numerical Green's Function" -- which helps speed
up calculations.

To verify program accuracy I have computed the radiation
efficiency of an ideal 9m monopole over a perfectly conducting
ground. The results are accurate to within less than 0.25%.

Obviously my previous results are no longer valid, So will
have to re-calculate all the test antennas.

Frank

I'm glad - most folks here ignore it. :-)

> I understand that your argument involves the energy that enters the
> line before it knows anything about the load, the energy that enters in
> an initial transient, but unless you can show that nothing happens
> during the initial transient to deliver some or all of that initial
> energy to the load, your argument has a hole.

Let's return to the one second long lossless transmission line.
From a 100 watt transmitter, at the end of second number one,
the line will contain 100 joules and the load will have accepted
zero joules. Since the load is rejecting 1/2 of the incident energy,
at the end of the 2nd second, the source will have supplied 200 joules,
there will be 150 joules of energy in the line, and 50 joules will have
been accepted by the load. If the source is equipped with a
circulator+load, this is steady-state with 150 joules of energy stored
in the transmission line.

At t=0:
zero joules zero joules
100w--------one-second long feedline------load rho^2=0.5
Pfor=0--> <--Pref=0 Pload=0

At t=1:
100 joules zero joules
100w--------one-second long feedline------load
Pfor=100w--> <--Pref=0 Pload=0

At t=2:
150 joules 50 joules
100w--------one-second long feedline------load
Pfor=100w--> <--Pref=50w Pload=50w

> You're presupposing that there is some energy that enters the line

> reflected wave?

Yes, at the end of the 2nd second, the source has supplied 200 joules
and the load has accepted 50 joules. That leaves 150 joules left over
that cannot be any place except in the line according to the
conservation of energy principle. In a circulator+load system, we

have reached steady state with 150 joules in the transmission line
that will not reach the load until after the source is powered down.

> The argument is circular.

Proving that confusion exists. It's actually not circular. It's
based on cause, effect, and the conservation of energy principle.
I apologize if I have not explained it in a way that is easy to
understand. Please bear with me.

It's all linear cause and effect. With an ideal auto-tuner
at the source, none of the reflected energy is accepted back by
the source. Half the energy incident upon the load is rejected. There
is no other place for the extra energy to be except inside the
transmission line. I have an EXCEL spreadsheet that might help you
sort all of this out. A copy of its output is available at:

If you can call a 20 feet long antenna a 'long wire', it is a 'long wire'. :-)

The EXCEL spreadsheet corresponding to the above can be
downloaded from: http://www.qsl.net/w5dxp/1secTline.xls
It includes a graph of forward power, reflected power,
and joules stored in the transmission line.

And ever so slowly we creep up on the *actual* point....

pick a freq, pick a mode, pick a language, pick a moment in time.
Nothing is perfect and CW or no CW, it's about circumstance, not code.
Then again, you can back it up one more and acknowledge the foolishness of
the whole CW argument.
As it stands, hams are so crazy they somehow think they are the only hope
for mankind.
I pray that farce never becomes fact!

Everything has it's place.
Ham radio is a novelty. CW is a novelty within the same. That's all....
As long as there are 40wpm ops out there that can't program a radio, it's
just a bunch of
ding-dongs arguing amongst each other, looking like a bunch of ding-dongs.
And it goes both ways.... no reason to ditch CW but this "my tapper is
faster than your tapper"
stupidity is just phallic and pathetic. Which finally brings us to the
overall problem...
As usual, the last word in any hammy hashing is the same.
Control freaks needing to feel in control, and the subject matters not.
That's why these goofy threads carry on forever.

Well... no, I got the point just fine. I can't imagine being surrounded by Spanish-speaking people needing a code interp, or being on a CW freq anyway, while some emergency happens to be taking place. And yeah, I'm elite like that... I have a gift for gab... just like a monkey can be trained to tap out a code of communication, I can parrot what I hear. It [or 50wpm CW] isn't intelligence in any way, it's just a stupid circus trick. Once again..... this wasn't or isn't the issue anyway... No one said there were no pros to the mode, just that the whole "save a life" thing is laughable. This argument jumps from an issue of speed, then to the generation gap, then to simple name-calling banter. It's quite humorous and totally stupid. Kudos to the OP troll! LOL

> The "Sky wave" radiated power represents
> only about 35% of the total input power.

==========

This should have been obvious from the radiation pattern of a vertical
antenna above ground. For all antennas less than 5/5 waves in height,
maximum radiation always occurs along the ground, ie., at an elevation
angle of zero degrees, ie., the ground wave. The take-off-angle
computed by Eznec-type programs is misleading in this respect.

==========

To repeat - I'm primarily interested in the difference between the sum of (antenna + radials impedance), and the antenna impedance, at frequencies around 8.1 MHz and 24.3 MHz, corresponding to an antenna height of 3 metres.

Thanks for keeping me posted.

Reg.

And for the millionth time, all you control/speed freaks just don't get
it..... If I could take down a message in CW at 200wpm in High German,
guess what? It'll take me hours to locate a German to translate it. SO.....
shot down yet again, a big burning ball of fire falling from the sky beepin'
SOS till ya hit the water right next to a burning boat...

Let's get back on point please. The question was if you had to use CW to
save a life, would that person die?
The answer is simple. If the person in question knows CW, then no, and if
the person in question doesn't know CW, then yes.
How hard is that? Why can't everyone keep to the issue?
rb

Ok.... you just ruined your whole argument.... you're now comparing
commercial and professional ops to amateur ops.
What is your point? The issue here is hobby radio operated by hobbyists.

The dark question has yet to be asked anyway... "Should amateur radio ops be
held to professional standards?"
Or maybe it's something about saving a life with CW... it's kinda muddy at
this point....

Excuse me? If you are going to operate on a worldwide basis, you should be
well versed on world languages so you don't have that problem. Ask any
hi-speed op and they should agree.
The funny part being most all foreign ops know English and most US natives
are small appliance bulbs in a world of Xenon driving lights.

LOL.... I assume you think you've made a point at any time?

It's a simple yes or no question....
If you had to use CW to save someone's life, would that person die?
Stay on point please.

Sheesh, why would we be in the CW band in the first place, and then why
taking down code or voice in a foreign language we don't understand?
That Mister, *must* be the epitome of ham....

You know, there are children starving in South America, Babies being
slaughtered at birth in India, and you
think some stupid ham op parked in a chair in poshville USA has a clue about
anything that really matters?
Oh! I know CW, I know CW! I passed a message once and saved the world! And
for the next 30 years I bumbled
around in my back yard drinking beer, eating donuts and doing nothing for
anyone except my own self.

Arrogant Americans lost in space.
That's thick.

There is quite a bit of on-line info on 2.4 GHz helix construction, and we built two of the versions that have the most complete photo and detail coverage (33mm and 42mm form dia). Neither worked worth a damn, despite all the effort put into their construction. Then we built the Biquad, which worked very well, and finally the can-type waveguide or "Cantenna" was the simplest and worked the best (use a 3/4 liter can that's 84mm dia, and at least 145mm long). The helix might be good if you have the ability to construct a self-supporting bare-wire helix, but the types wound on PVC pipes with vinyl insulated wire just don't work - - worse, actually, than the simplest 1/4-wave whip. Use a Wi-Spy Spectrum Analyzer to test performance with the antenna under test connected to your wireless router. A more accurate (but more expensive) arrangement is to use the Wi-Spy and an internal coupling antenna inside a shielded box, with a variable attenuator good to 2.4 GHz between the antenna under test and the Wi-Spy. Using this configuration, my results put both the Biquad and 84mm cantenna at +6dB, a 1/4-wave whip at 0dB, a 1/4-wave whip and groundplane at -3dB, and both Helicals at -7 dB. The Cantenna has better directionality and so was preferred over the Biquad.

Chuck, W6PKP

Bam... burnin' beepin' ball of fire trailing smoke to the white bubbly patch
in the ocean.... [next to the beepin' burnin' boat]...

Let's get with it people.... are we have a commercial radio argument or an
amateur radio argument???

If commercial then we all agree, argument is moot.

If amateur, it doesn't matter as it's just a hobby, argument is moot.

Make up your mind folks. Either this is a stupid argument or it's a stupid
point to argue.
[hint: its the one that's stupid]

I thought it was illegal to change modes during the EMF stage... ??
You should be able to remodulate your carrier to offset the gravimetric
effect on the signal
as it nears subspace. I scavenged a modulator wheel from an electronic piano
and work it with the left
hand whilst straight-keying with my right, as obviously this can't be done
with a keyer or bug of any kind.
Manual manipulation of each character's component time/phase is a must to
get a synch.

Good call. Admit nothing, deny everything.

Hey, if you had to use CW to make chicken salad for a starving Latvian,
would that person starve to death?

Yeah, those "real" radio ops really have it tough, don't they? There should
be a reality show called
"Two-Way Trauma: Life in the radio room."

Welp, when the AF took the airplanes away from the Army in 1947...

...this guy named Sikorsky came along and sold them some helicopters.
Anyway, they were a lot of fun and the idea really caught on. Now the
marines have them, too. Robesin says he worked on helicopters in some
capacity, and got hisself involved in 7 hostile actions.

The aluminum skin of a C130 is sort of hard to see through. The only craft that I ever saw with a glass underbelly was a tour boat in Florida.

But you can rest assured that neither robesin nor the CAP was flying that C130.

20 is SLOW. But the only way to learn 35 or 40 is to learn 10, 15, 20 etc.
And the best way to do that is get on the bands and DO it instead of making
rude noises at the people who CAN.

Phonetics on SSB are usually a lot slower than 20wpm, though.

We have three tests her in Canada now. The Basic gets you on the air.
If you get an 80% or higher score you get HF privileges with that.
You're limited in power and must use commercially built, approved gear.

If you want to roll your own gear or put up a repeater or something, then
write the Advanced. You'll get full HF privileges.

If you want to be known as morse proficient, then take the code test.
That will get you on HF even if you just PASSED your Basic. But if you
already have the Advanced, then it will get you a nic shiny morse
endorsement and a sense of accomplishment.

And no, the sky didn't fall any further than it already did when we
dropped the code requirement for Basic and made it VHF only.

Well, it certainly happened to me. Of course I can't say whether it
actually SAVED any lives. Because maybe they would have been saved
anyway, though it sure helped that I could figure out what was wrong.

But you see, a lot of ships used CW at that time.

> And yeah, I'm elite like that... I have a gift for gab... just like a

50wpm is relatively easy. Now back in 1975 when I was out on Sable
Island, I broke in on some guys on 80m with my nice new computer,
programmed to send morse from the terminal keyboard (but still requiring
a human ear to hear). They were going 65 and wanted to know if I could
"copy the morse code." One kid there used to QSO me and he'd start out
at 60 and ramp up. He was 13.

Well, to be honest, I leave my keyer set at 25wpm. That's a good steady
speed for general working. I'm only likely to speed it up if I'm in a
contest or something.

I have an MFJ-1026. The little noise whip that came with it had the wrong thread in its base, but no huhu, I just wedged a pen top in beside it to hold it against the pin. Sometimes it's no help, but other times it's spectacular, especially with some big splashy TV birdie that I get here a lot (I think it's in the building here but there are 45 suites, 15 of them on the back of the building where I am and a lot of commercial garbage within a block. That TV birdie can be 20 over 9 on my old Ten Tec 546B (which has a very parsimonious S-meter) on 75 and I can drop it to inaudible in the S4 hash.

Haven't tried the Timewave job, but they both work on the same principle, which is to pick up the noise with a separate antenna and amplifier and vary the gain and the phase until you cancel it out against the version from the main antenna.

It has certainly helped me work a number of stations that could not be heard without it.

Hello Andrew.

About your 75ft (22.86m) delta loop (vertical above ground).

For 80m, the loop is relatively small, so you can omit transmission line effects (to get an approximate value). The impedance consists of the wire resistance, radiation resistance and the inductance.

I expect the inductance to be about 28uH and the radiation resistance about 0.8 Ohm (series equivalent circuit). So your loop behaves at 80m as an inductance with impedance of about j660 Ohms. When you connect this to a 75 ohm line (via a 1:1balun). Most of the induced voltage falls across the inductance.

Using a 3:1 balun will give a significant improvement (in order of 6dB). Now the load for the loop is about 700 Ohms. In fact, your balun is good for 80m.

You may reduce the turns, since a reduction of the primary inductance to about 100uH is no problem. Reducing the turns may reduce capacitance between the windings improving balance. If the noise that you are receiving is above that of your receiver, everything is OK. You do not need an antenna tuner. Don't worry about mismatch. The only need for a tunable filter or antenna tuner is to reject strong signals that may overload your receiver.

For 40m the situation is a somewhat different. Now the wire length is about half a wavelength and the current will not be uniform anymore, so general inductance and radiation resistance formulas do not apply. It is possible that the capacitance between the wire ends (also via ground) may reduce the self resonant frequency of the loop. Your antenna may be capacitive.

I think the best way is to find out whether the received noise exceeds the receiver's noise floor. If at 40m still the received noise is dominant, your antenna is OK. Don't be afraid of mismatch. If performance is worse at 40, you may increase the turns ratio. Make sure that your balun is constructed well to avoid that interference coming from domestic equipment is guided to your loop via common mode transmission along your 75 Ohms cable.

If the signals and noise are far above the receiver's noise floor (check with attenuator), you may decrease the size of the loop. This will give better performance on the higher frequencies. Since inductance reduces more then the received output voltage.

With respect to transmitting, you can convert such a loop into a narrow band transmitting loop. In that case you need a tuner to correct the mismatch. The mismatch is that worse, that if you would correct the mismatch just behind the transmitter, most power will be dissipated inside the balun and or the 75 Ohms cable. In that case tuning the loop in combination with a inductive coupling will give good results (even for this loop). The disadvantage of this setup is that your tuning capacitor must be located at the loop.

Andrew, I hope this information will help you somewhat.

Best Regards and Good SW listening.

I have enhanced that spreadsheet such that the resistive
load on the one second long lossless 50 ohm feedline is
a variable entered by the user. Please note the graph
of forward power, reflected power, and joules stored in
the feedline (chart1). The enhanced file is available at:

My ISP has just re-connected the usenet feed after cutting it on Friday. It seems it happens each month? Go figure! Anyway:

Thanks for the feedback on the 6m elements and the 4 ele SteppIR. I want to go for the 3 ele. with 6m passive ele. because the boom length is the same as my existing beam. I could (just about) fit a MonstIR into the yard, but I don't want to get a beam antenna that big. My neighbours have come to terms with the metal monster, as-is. If it got even bigger, I think I would have a bit of a problem with them. I can always change it to the 4 element and then maybe the MonstIR so they would have the antenna 'grow' on them. My tower is tilt-over and crank-up so antenna work is quite a bit easier than climbing each time.

My current beam has a rotatable dipole on 40. For me it is just neater and more convenient than having an inverted-Vee.

Another big advantage for me with the SteppIR is that it is mostly fibreglass tubing so corrosion will be less of an issue.

40m through to 6m with one feeder! Luverly!

The source is relying on an ideal autotuner to
terminate the line with a 50 ohm Z0-match.

> The source can accept power from the reflected wave, right?

No, there is an ideal autotuner on the output of the
source. *Zero reflected energy reaches the source*. The
SWR between the Source and the Autotuner is 1:1 just
as it is in any properly tuned antenna system.

So how are you taking into account the stored energy in the ideal autotuner? Even if it's perfect, there's energy stored in the fields of the impedance transforming device. Are there 0J in the tuner? If not, how does the impedance transformation take place?

Dan

The ideal autotuner is lossless. The delay through the
tuner compared to one second is negligible. The energy
in the tuner components is negligible compared to 300
joules.

The principles are just as easy to comprehend if the
tuner is replaced by a circulator and load.

Since the Z0-match is achieved at the ideal autotuner
input, just consider the lossless autotuner to be part
of the one second lossless transmission line system.

The solution to that problem is to get a much taller tower so the
antenna is further away and therefore looks smaller. ;)

Listen here... I will not stand by and watch millions of innocent people die needlessly as
more an more people shun the gift of life by scoffing at CW.
It's genocide I tell you, and the government just sits by and watches it happen!!

Sorry... my bad... is it 35 now? I stand corrected.

Back to the chant...

If you can't do 35wpm, you should stay off the bands!!
Seriously people, think about it... do *you* want blood on your hands
because you're a slow-beepin loser?
Lives are on the line, in case you aren't paying attention.

This is serious business and requires a dedication as if it were... your
only purpose.

Unmotivated 25wpm losers need not apply.

Huh? How can a fast CW op *not* save a life? Have you read this thread at
all?
CW = Gift of Life.
Fast CW = Hand of God.

It's in the Extra Class manual....

> And that's why I'm watching TV from a 12ghz satellite signal right now.

3205. Re: Mismatched Zo Connectors

Newsgroup: rec.radio.amateur.antenna
Date: 2006-08-29 00:28:37 UTC
From: "n3ox.dan@gmail.com" <n3ox.dan@gmail.com>
Message-ID: <1156811317.904136.25960@h48g2000cwc.googlegroups.com>
Source record: 53591

What's the complex Poynting vector in the tuner? Why should I believe that the delay through the tuner is negligible? Why should I believe that the stored fields are negligible? It's not obvious to me.

For that matter, why does the ideal autotuner not reciprocal? The impedance in the presence of the standing waves at the tuner-line junction is R+jX. That is transformed by the autotuner so the source sees 50 ohms, but that also means that the output impedance of the generator is transformed as viewed by a wave coming down the line.

It's not transformed to infinity. If it is a circulator and load, this is a distinctly nonreciprocal system. If it's a tuner affecting a match, it is reciprocal. If your definition of an ideal autotuner includes the nonreciprocity, please send me a schematic of such a device.

I think I calculated the Poynting vector for this situation, I think the Poynting vector divided by the group velocity of the waves and integrated over the area of the coax gives the energy density per unit length in the steady state, and if you've tuned the line length so that the imaginary part of the Poynting vector goes to zero then the explanation you give falls apart.

The tuner matters here. This is the problem with English language discussions, especially disagreements, about electrical systems. "There exists an ideal autotuner at the input" is insufficient specification of the mathematical problem. If you place a device that does everything you say it does at the source-line junction, maybe you do get 300J in the one-second line.

Why isn't it reciprocal? Why is its phase shift negligible? Is it just because it's physically small? I seem to remember a certain hotly contested paper that I would think would have certainly put that sort of idea out of your head. I think the crux of the misunderstanding is in the tuner. I think it has stored energy and nonnegligible phase delay, else it is non-reciprocal and dissipative (circulator+load).

What *IS* an ideal autotuner? I think you've stuffed too many conditions into its operation for it to be a physically realizable device. I'm pretty sure that it breaks the time reversal symmetry of the system. Send out a pulse into your one second misterminated line via your ideal autotuner. Wait half a second. FREEZE! Now run the film backward while obeying the rules of your autotuner. The pulse doesn't go back into the source. It bounces. What's up?

73,
Dan

The delay calculates out to be in nanoseconds compared to
the one second delay in the lossless line. The stored
fields calculate out to be in microjoules compared to
the 300 joules stored in the one second long feedline.

The real question is, allowing for all the things to which
you have objected, why is there very close to the number
of joules in the feedline necessary to support the forward
and reflected waves? What makes you think there are not
enough joules in the line to support the forward and
reflected waves?

> For that matter, why does the ideal autotuner not reciprocal? The

It can be proved that a 50 ohm Z0-match, because of destructive
interference on the 50 ohm side, reflects 100% of the reflected
energy back toward the load.

> It's not transformed to infinity. If it is a circulator and load, this
> is a distinctly nonreciprocal system. If it's a tuner affecting a

> includes the nonreciprocity, please send me a schematic of such a
> device.

Please read the Worldradio magazine article from my web page.
What you are calling nonreciprocity is merely destructive
interference on the source side of the Z0-match and constructive
interference on the load side of the Z0-match.

> I think I calculated the Poynting vector for this situation, I think

> the imaginary part of the Poynting vector goes to zero then the
> explanation you give falls apart.

Not if one deals with the forward Poynting vector and reflected
Poynting vector *separately* as does Ramo/Whinnery.

Pz+ = 200 watts of forward power in a matched line.

Pz- = 100 watts of reverse power in a matched line.

Superpose the two coherent waves and count the joules in the
superposed waves.

> The tuner matters here. This is the problem with English language

> "There exists an ideal autotuner at the input" is insufficient
> specification of the mathematical problem. If you place a device that
> does everything you say it does at the source-line junction, maybe you
> do get 300J in the one-second line.
>
> Why isn't it reciprocal?

Because a Z0-match allows energy flow in
only the forward direction. That's how antenna tuners work.
Destructive interference keeps reflected energy from flowing
past the Z0-match toward the source. That's also how 1/4WL
thin-film anti-reflective glass works.

> Why is its phase shift negligible? Is it
> just because it's physically small?

All it has to do is shift the impedance from 300 ohms to 50 ohms.
A few microhenries and a few picofarads will do that. Its phase
shift would be in the nanoseconds.

> What *IS* an ideal autotuner?

It's a concept to be thought about and discussed. If one accepts
a one second lossless feedline, why not an ideal autotuner for the
sake of conceptual discussion? Then a real autotuner can be
substituted and the losses, delays, and energy components estimated.

But like I said, the concept that I am presenting doesn't require
the ideal autotuner. It is actually easier to understand using
a circulator and load. There is exactly the amount of joules in
the transmission line needed to support the forward and reflected
energy waves.

I certainly didn't say that. The steady-state voltage and
current component values have to exist for 100% destructive
interference to occur at a Z0-match. On the source side of
the Z0-match, in order to eliminate the reflected energy
wave, two reflected wave components are required to be
traveling in the same direction, be equal in magnitudes
and opposite in phase. Short pulses make those conditions
impossible.

In your above pulse example, there is no interference at
the impedance discontinuity and therefore a Z0-match doesn't
even exist. A Z0-match depends upon a steady-state supply
of RF waves.

A Z0-match at the input of a tuner works exactly like the
1/4WL thin-film anti-reflected glass coating. If one sends
a 1/2WL pulse of light at that piece of glass, there will
be reflections. Anti-reflective glass depends upon a
steady-state supply of light waves. One of the cancellation
components is 180 degrees older than the other one.

Let's return to the Signal Generators equipped with Circulators
and Loads (SGCL). Would you agree that the feedline contains
300 joules in the following example?

200W SGCL----one second long lossless feedline----100W SGCL
200W--> <--100W

Good on ya then! Do upgrade whenever you can, coz hammin' can be fun if you
can find a decent bunch to hang with.
Learning 5wpm is pretty easy and gives you a new "toy" or "language" to play
with if you are so inclined.
The big plus being the new privileges and theory, and all the hi-tech
progression in radio going on in the 21st Century!
There's lots to get into.
Gud luck,
rb

It sucked.

Just got a message on the somalia reflector today. Seems the al qaida
is well liked in somalia because the country has been through 15 years
of chaos and lawlessness, and the islamists are now imposing their law.
I guess any law is better than none.

Reminds me, in part, how hitler came to power.

Piggy-backing off this thread, please: When I was an EMI technician some years ago, we used conductive anti-seize on (most) hardware that was in a conductive path, such as grounding straps. I was surprised to discover that some/most anti-seize is non-conductive; you can daub some kinds on the benchtop and stick ohmmeter probes in it -- nothing happens. I figured with its metal content, surely it would all be conductive, but not so.

I have no idea what implications this has for the OP's Butternut and would welcome comments.

You raise the difference between improve conductivity of a connection
and anti-seize compounds.

What the other person probably needs is not (as he asked) anti-seize,
but conduction enhancing / protective paste, which is usually
something link zinc or aluminium dust in a silicon grease carrier (for
aluminium). The particles help to create a current path between the
parts under pressure, and the silicon grease helps to prevent water
getting in forming an electrolytic action and consequent corrosion.

I don't think your ohmmeter test is a good one (ie sticking probes in
a puddle of stuff). The particles work by being crushed into the
adjacent surfaces under the pressure of the mechanical connection.

In the absence of stuff made for the specific metals, I find that
marine grade grease (withstands elements better than chassis grease)
or silicon grease (expensive) applied to cleaned parts (most
important) is often adequate, and usually better than nothing.

A stainless steel brush is handy for cleaning joint parts, some scotchbrite pads are useful, but they embed in soft materials, and ordinary steel wool is the worst for embedding.

Hi All.....

I have just bought a Yaesu VR5000 receiver/scanner and while looking round
for a wideband antenna
came across the good old log periodic but what a price!!!, circa ?200+.....

I have a discone but it`s not a lot of use up around the 2gig area (or
anywhere else!!) so i thought i
might have a go at making my own, the magloops are working great as is the
QFH 137megs
weathersat ant, thanks to everyones assistance!.....

Is there any software around to design a log periodic to around
2400megs??.....i`ve found some but is there any better?..

Regards...

Lee......de G6ZSG....

Hi Lee,

Simply build a discone to the scale of 2GHz. The reason why the
present one might not work is that if it is designed for a very lower
base frequency, it is TOO BIG.

Discones can be as wide banded as over a 10:1 frequency range, but
this is for matching (certainly useful, but this does not necessarily
make it usable).

For instance, if you have a discone that has a low frequency design of
450 MHz and claims to go as high as 2GHz; then it may well match at
those frequency extremes. On the other hand, at 450 MHz it is looking
out at the horizon, BUT at 2GHz it is looking into the sky. The
higher the frequency, the more the most favored direction climbs up.
In other words it becomes deaf unless you want to hear an overhead
satellite. This may be the source of your disdain for your current
discone.

Build a Discone whose lowest frequency would be around 1.2 GHz.

How do you know what the lowest frequency is? Measure one of the
skirt elements (the skeletal part of the cone). It should be a

quarter wave of the lowest frequency of intended use. In this case, 1.2GHz, that would be 6 cm or so. The high end would then comfortably range up to 2.4 GHz, match, and still look at the horizon.

Of course, the simple ground plane at 2GHz would work as well, unless you really need widebandedness (and it would probably work even then). Simply observe the simple geometry of keeping the element no longer than 5/8ths wavelength at the HIGHEST frequency you plan to monitor.

If you still want a log periodic, simple scaling will always work. However, remember that scaling must be applied to ALL physical dimensions (this means element diameters too).

Yes, thanks for the info but i would like a little more gain than a standard discone gives...going to a parabolic discone would be the alternate option but a little too involved....

A Heathkit CanTenna would be ideal for that setup.

In case you missed the subtlety, this NG is for licensed radio
amateurs, not CB'ers with illegally modified rigs and/or amplifiers.

Who's gonna see a single want ad in 300 postings about nothing?
Who wants to pilfer 300 postings about nothing to find a sale ad?
On the Somalia thing,
Do you mean extremists/terrorists that claim to follow Islam, or just basic
Islamists?
It looks like you mean the former.

Please understand that Al Qaeda is a group of terrorists/extremists, it
doesn't matter what religion they
claim to follow.

Source record: 53620

We are mixing multiple topics here...

First, the OP asked about preventing mechanical seizure between two aluminum tubes... For this I prefer a molybdenum antiseize from the auto store, or similar... I had a System One beam in the air in Michigan for 25 years... The joints were lubed with the moly and then the assembled joint was taped with 3M - #33 tape and the ends of the tubes were plugged... When I sold the house and the beam came down the tape was still on, though starting to crumble, and the tubing only need a firm twist to slide the joints apart... The mating surfaces were clean and still had a shine.. There was an invisible film of the moly antiseize staining my hands and clothing after a quarter century...

Second, is the issue of blocking electrolysis between disimilar metals, eg. copper and aluminum... For this I would use the appropriate paste, NoAlOx is one brand... For copper to copper there is a different paste used..

Third is the issue of slow oxidation of aluminum which causes a high resistance joint - and possible mechanical seizure... In areas more prone to oxidation then I might prefer NoAlOx, or similar over the moly based antiseize for bolts... In Arizona aoxidation is a non issue... In Tampa oxidation is the only issue...

The last topic is increasing electrical resistance of the joint when the surface oxidizes... What the antioxidation paste has is zinc particles in suspension that when clamped between the two metal surfaces actually pierces the film of oxidation mechanically and creates a lower resistance path for current flow...

All you have to do (if you've got about 8 hours to spare) is go
through Google archives since before they bought it from
DejaNews several years ago. "Robitussin" has thousands of
postings in the same venal manner he continues to use...
especially his self-promotion as heroic USMC veteran which
he has never, ever proved through any third-party references,
digitized documents, or much of anything else other than his
own AOL home page and self-description on QRZ.

He is clearly into his own fantasy of imagined superpowers
without the aid of Stan Lee.

:-)

Illegal in the USA!!!

Buy a legal Cobra and live on 11 meters at 15 Watts PEP [the legal USA limit].
You may be making a public confession of illegal activity!!

An eight and 1/2 feet long SS whip is the BEST mobile 11 meter antenna.

"Sidetracked?!?" :-)

I put this message into the Captain ARRL Superpower Decryption
machine and the machine broke down.

Last I looked (which was yesterday) there were NO Public Safety
radio services which used "CW" for either "life-saving" or distress
calls. The USCG doesn't monitor the OLD 500 KHz international
maritime distress and safety frequency any more. International
Civil Aviation Organization long ago stopped any need for carrying
"CW"-proficient air crew on over-ocean flights.

This "vital need" of maintaining a "pool of trained (morsemen)
operators" in the mighty amateur radio (militia?) ranks is a
wigment of olde-tyme morsemen's imagination.

In truth, I haven't checked out the Civil Air Patrol. Maybe they
have some kind of "need" for morsemen even though they use
121.5 MHz for emergencies just like all the CIVIL airways do.
[transponder squawk to 77 or 7700 if that is installed; 243 MHz
if a REAL military aircraft]

We'll have to see what the "pilot in command" of a TN CAP
two-seater has to say on that...if he isn't "busy" with his
"life-saving air patrols." :-)

wrote:

>Yes, thanks for the info but i would like a little more gain than a standard
>discone gives...going to a parabolic discone would be the alternate option
>but a little too involved....

Parabolic discone??!!!?? Involved is not the word.

Hi Lee,

Everyone wants more gain. You don't say why and that may negate
wanting gain.

At the frequency you are desiring, performance is very much limited to
line of sight and even 2M handhelds with rubber duckies can work the
Space Shuttle an hundred miles up.

Consider the downside of gain: you are a tourist at the Grand Canyon
and you put a telephoto lens on your camera (high gain). When you get
home and show your pictures to friends, they might ask why you went to
the Grand Canyon but took pictures only of the river bed at the
bottom, or a cactus on the ridge. Too much gain for the intended use
which was to show the ENTIRE canyon in one shot. This would take a
wide-angle lens (very low gain).

Anyway, simple scaling works. Just research the model of antenna that
gives you the gain characteristics you want, and scale to your band of
interest. The downside here is you may find that you have designed
yourself into a corner because you cannot find the right stock that
supports the dimensions. For a log periodic, this might not matter so
much, and especially for a receiver, but latitude is not generous.

Yes. But how much is there with the circulator load removed? (Not
replaced by an autotuner.) Numbers please.

Why you suppose I keep asking this question, Cecil?

Your statement is a personal opinion without technical content.

>> 200W SGCL----one second long lossless feedline----100W SGCL
>> 200W--> <--100W
>
> Yes. But how much is there with the circulator load removed? (Not
> replaced by an autotuner.) Numbers please.

OK, let's remove the circulator loads and replace them
with unknown devices or objects inside black boxes.

Here's the same one second long lossless feedline with
unknown black boxes connected at each end (where BB stands
for black box).

BB#1------one second long lossless feedline------BB#2
200W--> <--100W

Given: all conditions on the one second long lossless feedline
are identical in both of the above examples.

The laws of physics tell us that the joules in the two
lines with identical conditions are equal, i.e. 300
joules in these two cases. It doesn't matter what exists
or doesn't exist at the two ends of the line. 200 watts
forward and 100 watts reverse requires 300 joules/sec.

In other words, given a purely resistive Z0 and a properly
calibrated wattmeter, it is impossible to get 200 watts
of forward power and 100 watts of reverse power without
there being 300 joules in the one second long lossless line.
If there wasn't 300 joules in that line, we wouldn't
measure 200 watts forward and 100 watts reverse.

Well, let me ask, from the point of view of a potential noob to the hobby. What use is the code requirements?
I can't really see in today's era, the need for them? I've been surfing around looking at ham and talking to
an old friend that had a license and it look interesting to me.

But, given that many professional people like myself are stretched for time, what good does all the licensing
and code requirements do for you besides build up boundries to doing something new and fun?

I'm in a pretty technical field, and I study to keep up in that field everyday, the last thing I want to do,
is have to spend my weekends studying to talk on a radio. If less stringent requirements were there, I could
easily afford the tools of the trade, and would like to just jump in and start working with a ham setup. I'm
particularly interested in exploring the amateur radio/computer connections.

I have no problem informally looking up information and learning on my own (heck, that's what I'm doing in
the USENET group to begin with)...but, I just don't have the time for archaic rules, regulations and codes
that as far as I can see...really serve no real purpose but, to keep out busy people that might like to
participate.

Can you give me valid reasons as to what useful purpose in today's age they serve?

Thank you,

noonespecial

The 'use' is something you just can't understand. The 'use' is a commitment of time and talent which adds value to the license. The 'use' is investment.

Balance of original post has been REDACTED.

SURE!

But, EMT is a 'soft' aluminum and will require guying and/or other support. It is soft so electricians can bend it around corners.

> Why you suppose I keep asking this question, Cecil?

Because you believe in intelligent waves that somehow
sense their ultimate fate and therefore know how much
energy to carry or not?

Wave#1: "I am going to be dissipated in a circulator
load and therefore, I must contain N joules of energy."

Wave#2: "I am not going to be dissipated in a circulator
load and therefore, I must contain zero energy."

Given the following two configurations where BB stands
for Black Box:

BB#1----one second long lossless feedline----BB#2
200W--> <--100W

BB#3----one second long lossless feedline----BB#4
200W--> <--100W

Given: All voltages, currents, fields, and powers
are identical in both systems.

Please present us with a set of Black Boxes that will
satisfy your assertions and result in different energy
magnitudes in the two lines.

In other words, you just can't come up with a valid
reason other than some emotional-traditional one, can you?

What is the return on that "investment?" Being good enough to
do 1930s radio operating? In a diversified HOBBY?

What you really seem to be saying is that "everyone has to do it
because you did it...so there, nyah, nyah..." :-)

> Balance of original post has been REDACTED.

You have been redacted.

You have been rejected.

You have been inducted.

Here's a news flash: The job of the FCC (the agency that grants
amateur radio licenses...and hundreds of others...) is to regulate
and mitigate all USA civil radio. It does not tailor ham tests to
some nebulous "tradition" of the Archaic Radiotelegraphy
Society (ARS). I.E., it has no reason to demand anyone take a
manual morse code test except under the lobbying by the ARRL.

If you want to "preserve" the ARS as requiring morsemanship for
all privileges below 30 MHz, then you need to make up a Petition
and submit it to the FCC. You can even ask them to RENAME
the ARS to Archaic Radiotelegraphy Society. The FCC allows
such petitioning. They even explain how to do it on their website.

Tell the FCC that you insist on maintaining 1930s standards of radio communication well beyond 2030 by keeping that morse code test forever and ever. The ARRL will love you for it. Go for it!

Motivating hams to be better hams is a good thing.

For example, if you were going to lose your internet if you didn't learn how to type and spell after a year, I'm sure you'd be learning how to type and spell. But since there is no requirement that you have to type and spell properly after a year, you continue on murdering the english language.

There's some real gems in there.

Lawsuits. Robeson sues people, or at least he says he does. In his last lawsuit, he got an Upper Peninsula attorney gratis, then made comments on who his free attorney's wife might be sleeping with. Meanwhile, the person he is suing has yet to be served.

"Bricks through windows, slashed tires, terrorized wives." These are bad things that happen to people who shoot their mouths off, as some people have been told they do. Mind you, Robesin isn't the one throwing bricks, slashing tires, or terrorizing wives. "Other people" do this sort of stuff.

"Dialing..." On Robesin's personal authority as a male nurse and failed Marine, he can make a phone call anywhere in the USA and have you picked up on his say so. Really.

"PUTZ, Putz, putz" Disagree with Robesin and you are a penis with a yiddish accent.

"PEDOPHILE, Pedophile, pedophile" If you disagree with Robesin and you give of your time to a youth group, you are a pervert.

"HOMO, Homo, homo" Disagree with Robesin and you are queer, with lots and lots of inuendo.

Robesin is a national hero, taking part in seven hostile actions as a Marine. Yet, his only overseas assignment is Okinawa. Never been injured, but discharged after only 18 years. Says he's retired. Says he's disabled. Says it's not medical. Says he has been rehabilitated by the VA. "Ask the VA."

Robesin got back into uniform as a Tennessee State Guard "officer" of some kind. Very short lived career.

Robesin got back into uniform as a Civil Air Patrol (CAP) "officer" of some kind. Says he's a Major now. Photo of him in a sage green (not blue) flight suit on his QRZ website. As far as I know, most CAP volunteers are involved in training youth/Cadets. Hmmmm?

Robesin got a vanity call, K4CAP, while in the CAP. The CAP HQ is at Maxwell AFB in Montgomery, Alabama. Then he gave it up. Look where his old call now resides.

Robesin got back into uniform as a male nurse. Says he doesn't wear the white dress uniform. Probably just regular pants and a v-neck lavendar colo[u]red top.

Robesin has military medals. He has lots of medals. Many of those medals he didn't earn.

Robesin used to be an ASSISTANT NCOIC of NMC MARS on Okinawa. Doesn't know the first thing about it. Doesn't know what a MOD is.

"MARS >>>IS<<< Amateur Radio" according to Robesin Yup, you heard it here first.

A well know amateur radio outlet had the owners daughter's photo featured in a prominent amateur radio publication. Robesin said she was selling "Something" but it wasn't radios. He's a swell guy.

Robesin can make comments all day long about how your children won't respect you. His child died from severe birth defects and he knows that no one will make comments about his children. He's a swell guy.

Robesin needs to talk to the wives. He needs to talk to Len's wife. He needs to talk to my wife. He needs to talk to Mark's wife. He wants to talk to them on the phone or in person. He wants to mail them. He wants to knock on my door to talk to my wife and posts partial addresses so you know to expect a visit. Now he makes jokes about Len and Mark's wife. He's a swell guy.

I could go on, but I don't have 8 hours as Len suggests...

So what's the real beef??? I disagreed with Robesin. He doesn't like the way I think.

So what's the real, Real beef? I don't think the Morse Code exam should be retained for an HF license in amateur radio.

I'll say it again ... INVESTMENT!!

If an activity is to have value it must have INVESTMENT.

Whether it be Boy Scouts, Girl Scouts, Little League coach, Soccer MOM, fishing,
poker playing, or just watching tv. All require INVESTMENT if it is to have value.

If you don't/can't make the INVESTMENT, find something else to become involved with.

It has nothing to do with hazing.

If you will read Part 97 (the rules that govern amateur radio), the
government doesn't care about you doing something new and fun. The section
on basis and purpose makes it quite clear that their objectives are quite
different. They want people knowledgeable in ham radio and who are
interested in expanding that knowledge.

Until and unless you have actually participated in amateur radio in a wide variety of aspects, it is difficult to asses which rules, regulations, knowledge, etc are archaic and which should remain as requirements. Notice that the majority of people advocating ditching requirements are those who have not yet passed those requirements, regardless of their age. Note that the majority of people advocating keeping the requirements have passed them and have experience in amateur radio again regardless of their age.

As far as "busy people" go, again refer to the basis and purpose as given in the rules. The government is not concerned about your choice of how you use your time. It has no bearing on what their goals are.

> Can you give me valid reasons as to what useful purpose in today's age
> they serve?
>

Every piece of knowledge has its uses. The difficult part is winnowing through it and decide what should be tested and what should not.

Here's why I think code should still be tested:
1. It is still one of the basic building blocks of ham radio. For example, one of the "hot" digital modes is PSK31. The developer drew upon personal experience and incorporated features derived from that mode to make a robust digital mode.
2. Because it is not "book learning", too many people will avoid it since it is different than the type of learning they are accustomed to. They will falsely think it is hard when in reality it is different. Requiring them to learn it gets them over that resistance hump.
3. Each and every mode has its strong points and weak points. Each of us that participate in ham radio should attempt to gain personal experience in those modes so that we know by that personal experience what those strengths and weaknesses are.

If you are interested, I could construct various scenarios where mode X is the best mode. However, unless you specifically want to know, I won't clutter up the newsgroup at this time with discussions that have been repeated many times by many people already.

Dee, N8UZE

LenAnderson, You have obviously made an INVESTMENT in your technical profession.
Make one in your participation in the radio service!!

Amateur Radio is a SERVICE!!! If you only think of it as a hobby your thinking
is flawed.

Here's another:

""SOMALIA, THE BLACK HOLE OF ANARCHY

BY AHMED Q. BURSALIID

In mid July 2005 The U.S. intelligence agents, working with local
warlords, have carried out counter terrorist operations to seize
suspects. "Somalia remains the theatre for a shadowy
confrontation involving local Jihadis, foreign Al Qaeda operatives
and intelligence services from a number of regional and
Western countries," says a report by the International Crisis Group
in 2005. The report says the "dirty war between terrorists and
counter-terrorist operatives in Mogadishu appears to have
entered a new and more vicious stage that threatens to push the
country further towards Jihadism and extremist violence unless its

root causes are properly addressed."

The Somali transitional federal government was formed in neighbouring Kenya in 2004 and moved into Somalia June 2005. However, the administration has failed to relocate to Mogadishu, the Somali capital, because the city was considered unsafe. Due to the insecurity of Mogadishu, the TFG relocated to Jawhar, which it later decided to move to Baidoa.

Warlords and leaders of Islamic courts have been fighting in Mogadishu for about five months. This led to the loss of hundreds of civilians and
destruction of properties. Somalia, which had been in a state of anarchy
for more than a decade, has once again gone to war; this war was somehow
different from previous ones. The nature of this war is seen to have some religious and political clash while previous ones were much related
to tribal and feudal conflicts. Each one of the conflicting parties is claiming that the other group is related to Al-Qaeda when the reality is
somehow different from that. After months of armed conflicts within the capital city of Somalia, Union of Islamic Courts took the lead with enormous points by eliminating the warlords who took hostage the country
and its people for 16 years.

United States of America, which earlier denied any allegation of helping
or giving hand to the warlords in the fight to weed out the Islamic Militia in Somalia shortly after the takeover admitted that it had been supporting warlords to destabilise the Islamic militia. America has been
an active player in the politics of Somalia, and until now its policy towards restoring peace and stability in the war -torn Somalia is somehow obscure.

Somalis believe that it is the right time to take advantage to restore the lost hope of good governance in the country as Union of Islamic Courts led by Sheikh Sharif imposed law and order on Mogadishu, which was seen neither for 16 years. Hundreds of families from overseas countries returned back to Mogadishu, the capital city of Somalia since the takeover took place.

At first Transitional Federal Government welcomed the political change, which took place in Mogadishu as the Union of Islamic Courts disarmed a pack of US-backed warlords that took the country and its people hostage for more than a decade. But soon after the Islamic Militia started to capture some other cities, the TFG warned the Union of Islamic Courts of
capturing farther cities. A big gap of political misunderstanding came

in between the Transitional Federal Government and the Union of Islamic Courts, after the president of fragile Transitional Federal Government requested peacekeeping forces from the African Union. As the new Somali constitution inked in Kenya says, "Peacekeeping forces should not come from the neighbouring countries (Ethiopia, Kenya and Djibouti)". Likewise, the parliament passed a motion, which it was requesting peacekeeping troops to Somalia without paying attention to the classification of peacekeeping forces from AU countries and of front
line countries. This has created an escalation of political crisis in Somalia. Ethiopia, which is the common enemy of Somalia has sent its troops to Somalia in an attempt to protect the Transitional Federal Government.

This time, Arab League took the political platform of Somalia to mediate
the two conflicting parties. TFG and UIC were invited to attend a mediation conference held on June 2006 in Sudan to settle their differences. After a reconciliation conference, presided over by Sudanese president Omar Hassan Albashir, the current chairman of Arab League, the reconciliation process derailed with unknown reasons but it is believed that Ethiopia was the main figure, which made the reconciliation process fail as the outcome of the meeting could not meet
the criteria of Ethiopia's plan to Somalia and then, President Abdullahi Yusuf Ahmed, a well-known pro-Ethiopian warlord and his loyal prime minister Ali Mohamed Gedi, a vet scientist started to advocate the
legality of Ethiopian Army presence in Somalia.

The Somalis are of the opinion that the involvement of Ethiopian Army in
the peacekeeping operations in Somalia could cause havoc and deterioration of the political condition of the country in any case as Ethiopia is an old aged enemy of Somalia in East Africa. While a vast majority of the Somali public strongly opposed to deployment of Ethiopian troop into Somalia under any pretext, president Yusuf's political stance towards the deployment of Ethiopian troops in Somalia is clear and also in action by denying the presence of Ethiopian troops in Somalia just to protect his presidential seat.

Since the reconciliation conference in Sudan derailed a number of ministers resigned due to the political misunderstanding between TFG and
UIC. Prime minister declared that he would be nominating successors of the resigned 24 ministers. In addition to that, the prime minister himself survived after the Somali parliament passed a motion of no confidence against him recently.

Moreover, Prime minister of Ethiopia Milez zanawi whose government earlier denied any presence of Ethiopian troops in Somalia told BBC

that
his government has sent troops to Somalia to protect the Transitional Federal Government from the Union of Islamic Courts. While on the other hand, Eritrea is also believed to be an active supporter for the Union of Islamic Courts. Somalis believe that the support from both Ethiopia and Eritrea respectively is much related to a proxy war in between them.
US government warned Ethiopia and Eritrea stop the proxy war they are playing in the Somali territory.

As long a 'Rare DX' uses CW, CW will live and thrive in the DX community.

A DX pile of 100 stations on CW occupies much less bandwidth than 1 SSB station.
The CW contact rate exceeds the SSB rate.

As long a 'Rare DX' uses CW, CW will live and thrive in the DX community.

It's your choice: if you want to play the DX game learn the rules including 25 wpm CW.

If you want to operate an appliance, but an appliance.

No. That's something you keep insisting on talking about. Try to keep your mind focussed on the fact that we're discussing the steady state. (Or as you might proffer, after the waves have "decided" what they're going to do.)

How about we just get back to the question. Energy in your 1 sec. transmission line, only with no load on the circulator (and no autotuner). How much? Explain. Try it!

> How about we just get back to the question. Energy in your 1 sec.
> transmission line, only with no load on the circulator (and no
> autotuner). How much? Explain. Try it!

I honestly don't know what happens when the third port
of the circulator is unterminated but it is irrelevant
because the steady-state forward and reflected powers
would not be the same. I concede to you the fact that
one can always make an example too complicated to
analyze presumably for the purpose of diverting the
issue. But why would you want to divert the issue?

The real question is: Do two identical feedlines with
identical signal characteristics contain the same
amount of energy as in the following two examples.
Again SGCL is a Signal Generator with a Circulator and
Load resistor. Z0 is 50 ohms and the load is 291.42 ohms.

200W SGCL-----one second long lossless feedline---load
200W--> <--100W
lossless
100W---tuner--one second long lossless feedline---load
200W--> <--100W

It is easy to prove that the first example contains 300
joules in the feedline after two seconds.

It is easy to specify that the conditions in the feedline
in the two examples are identical during steady-state.

Are you asserting that two identical feedlines with identical
conditions contain a different number of joules?

I have another example in another posting.

If one wants to know where the energy in the transmission
line came from, one must consider the initial transient
state. Let's take a simple example like the one W7EL uses
in his food for thought #1, a simple stub, except let's
make it one second long and lossless.

100W------one second long lossless feedline------open

During the first two seconds, the source pours 200
joules into the stub. After two seconds, steady-state
is reached and there is no net transfer of energy in
either direction at the source. Where are the 200 joules
that were sourced and not dissipated?

From: Dave <W...@comcast.net> on Tues, Aug 29 2006 4:38 pm

>LenAnderson, You have obviously made an INVESTMENT in your
>technical profession.

Yes, I have. Not only has it been intellectually rewarding,
it was also monetarily rewarding...for the last 54 years.

>Make one in your participation in the radio service!!

Kiss my yes, "Dave," I've "participated" in numerous radio
SERVICES of USA civil radio and in DoD contract work from
below LF to Ku-Band. In these previous 54 years I've
communicated from land, from the air, from the ocean
surface...even once "worked" a station ON the moon. Never
once in 53 years was I EVER required to either use or know
on-off-keying manual radiotelegraphy.

>Amateur Radio is a SERVICE!!! If you only think of it as a hobby your thinking
>is flawed.

"Dave," you are SO FLAWED that you can't think straight.
Here's the real story:

Go to the FULL Title 47, C.F.R., and LOOK at ALL the radio
SERVICES. The word "service" used in Title 47 is a
regulatory term denoting a type and kind of radio activity
being regulated under a Part. Go write the FCC if you
don't believe that. But, you won't believe that since you
are obviously stuck in some kind of "patriotic" pipe-dream
where you think a HOBBY activity is some kind of "national
service."

Look in Part 95, the Personal Radio SERVICES. In there you
will find the Citizens Band Radio SERVICE and the Radio-
Control Radio SERVICE. Those are all SERVICES, "Dave."

There is NOTHING wrong with having a HOBBY. It's a fine
hobby in fact. What is wrong, seriously wrong, with your
(observable) thinking is that US amateur radio is some
kind of quasi-military "national need" that is somehow
"important to the national welfare." It isn't. Amateur
radio is about as "vital to the nation" as CB or some
model airplane flyers on one of the 72 MHz channels.

Yes, HAMS get neat certificates from the federal government (suitable for framing) and like to go around saying "they are 'authorized' by the feds" as if that were some Nobel-laureate accomplishment. It isn't. The FCC is tasked with regulating and mitigating ALL United States civil radio. Since amateur radio transmitters emit RF that requires the FCC to regulate it. The FCC, or rather its predecessors (before 1934), decided that licensing was a way of doing that regulation. To get that license required taking a test. That TEST was never, ever any sort of academic achievement thing (FCC was never chartered to be an academic institution), just something to satisfy the FCC that a license applicant was sufficiently knowledgeable to get that license. Note: Satisfed the FCC...not the ARRL, NOT the nebulous "ham community" or even any "Hams in da Hood."

Have you got that straight yet, "Dave?" Did you take some kind of oath of "service" on getting your amateur license? Raise the right hand and repeat after whoever was prompting you on the oath? No? I didn't think so.

I took a REAL oath on 13 March 1952, "Dave," entering the United States Army. A Real SERVICE, "Dave." I did my "eight" and got an Honorable Discharge. From February 1953 to end of January 1956 I worked HF comms in Big Time radio. You can even download a photo essay of that from this link:

http://sujan.hallikainen.org/BroadcastHistory/uploads/My3Years.pdf

It's 6 MB and will take about 19 minutes download over a POTS dial-up connection. If you look closely at those 20 pages you won't find a single thing about "working CW" (on-off-keying manual telegraphy) yet the whole station ran 24/7 pushing about 220K messages a month. It would be IMPOSSIBLE to send that many (some of which were encrypted) by manual telegraphy unless the signal battalion was doubled. It didn't have to be because the messages got through and on-time. That was 53 to 51 years ago, "Dave."

What do you think the military uses NOW for communications? Data, "Dave," Data. High-speed data, "Dave," not some dinky 1200 baud amateur stuff. DIGITAL. Digital can be on-line encrypted and on-line decrypted securely.

You show me where the REAL Services use manual radiotelegraphy, "Dave." They don't. It is voice and/or data, most of it in the field done DIGITALLY.

>/s/ Dave, BSEE, Program Chief Engineer-retired, LGM-118A(RS), MK21/W87

WTF, "Dave?" So, you tacked on a bunch of undescribed acronym things supposedly project numbers or IDs. Are we to be "impressed?" I'm not. I've worked alongside and for PhDs who

didn't bother with IMAGE and all that rank-status-title BS...
WE got the job done, working together.

Amateur radio MIGHT get something done working together. But,
you olde-tymers won't. You have to RULE, holding fast to the
traditions of 50 to 70 years ago...because YOU and all the
olde-tymers had to do it so everyone else has to...and all
you olde-tymer morsemen think that "CW" is somehow "best."
It isn't "best." If you really have a BSEE instead of just
PR BS about morsemanship, you would realize that.

><http://www.strategic-air-command.com/missiles/Peacekeeper/Peacekeeper...>

"Dave," amateur radio isn't about missles. Save your energy
for donating DVDs of "Strategic Air Command" (starring Jimmy
Stewart) to give to impressionable youngsters.

I've been in the smoke-and-fire trade of rocket engines for a
little while (Rocketdyne Division of Rockwell International).
Trust me, rocket engines do NOT use manual radiotelegraphy.
BTW, SAC is GONE, "Dave." A whole reorganization in the USAF
some time ago. No more "oil burner routes" or flying out to
loiter near the USSR (the USSR is gone, too). BTW, there
were SSB transmitters emitting 12 KHz wide RF long before
SAC got the single-channel SSB stuff to use on such
loitering. I know, having to keep a few of those REAL SSB
transmitters running correctly.

Now, "Dave," I can't fault on-off-keying CW any. The key
fob for our 2005 Malibu MAXX uses that. Yes, the last
vestige of high-speed CW (REAL CW) done digitally. Done
by the hundreds of thousands all over the country daily.
Nearly all of them operated by unlicensed NON-MORSE-TESTED
civilians! That Chebbie got in our garage courtesy of
"investments," "Dave." Investments in REAL work, not
playing like big-time 1930s radio ops "jobs" of a long-
past age by AMATEURS.

Dee, the "rules that govern amateur radio" are the ENTIRETY
of Title 47 C.F.R. I don't care that the ARRL pushes ONLY
Part 97. Part 1 has plenty about amateur radio as well as
a few other Parts. Look it up. It's free at the US Government
Printing Office website.

>The section
>on basis and purpose makes it quite clear that their objectives are quite
>different.

The "objectives" of the FCC are to regulate and mitigate ALL
civil radio in the USA, Dee. That's what the Communications
Act of 1934 and the Telecommunications Act of 1996 chartered
them to do (plus quite a bit on wireline comms...which don't
apply to amateur radio).

The "Basis and Purpose" has a lot of POLITICAL boilerplate
in it, just like most of the other Parts for other radio
SERVICES. Get real.

> They want people knowledgeable in ham radio and who are
>interested in expanding that knowledge.

The FCC is mainly interested in all radio services' users
FOLLOWING THE REGULATIONS, Dee. That's their job. The
FCC doesn't "want" people a certain way, only to FOLLOW
THE REGULATIONS.

>> I'm in a pretty technical field, and I study to keep up in that field

"George," you've got a whole bunch in this forum who think
that amateur radio is some kind of veddy formal "JOB" with
absolutes on THE WAY THEY DO IT. It's almost draconian in
the insistence of "correct proceedure." No one will get
fired from that "job" if they don't use "correct" ways but
the way they blabber on you'd think they were "supervisors."

>Until and unless you have actually participated in amateur radio in a wide
>variety of aspects, it is difficult to asses which rules, regulations,
>knowledge, etc are archaic and which should remain as requirements.

Horsepuckey. Dee, "George" is talking about GETTING INTO
amateur radio. Don't give us this olde-tymer morseperson
"I've operated all the modes there are" stuff. Dee, I've
operated lots more modes on radio than YOU are allowed to
as an amateur.

Manual morse code ability IS an ARCHAIC mode of communications
Dee. ALL the other US radio services have either dropped it
for comms or never bothered with it in the first place. ALL.
The ARRL and the olde-tyme morsepersons insist that the manual
morse test "MUST" remain to "show something" about commitment
and dedication. To WHOM, Dee? To YOU? To da Hams in da hood?

>Notice
>that the majority of people advocating ditching requirements are those who
>have not yet passed those requirements, regardless of their age.

Dee, before you get to the downright-bitchy stage, may I remind
you that some of us professionals in radio and electronics
NEVER BOTHERED WITH AN AMATEUR RADIO TEST? I got my First 'Phone
in 1956. Considerably more testing involved than a ham license
test then. Could YOU get a GROL now? Could YOU get a job
working with radio hardware?

>Note that
>the majority of people advocating keeping the requirements have passed them
>and have experience in amateur radio again regardless of their age.

Yes, nine-year-old Extras possess the maturity and wisdom of
the ages, all through having taken that morse test and gotten
that magic certificate (suitable for framing).

>As far as "busy people" go, again refer to the basis and purpose as given in
>the rules. The government is not concerned about your choice of how you use
>your time. It has no bearing on what their goals are.

Dee, you are LECTURING again. [just how long have you been
in ANY radio?]

Dee, go look at some 1990 documents on the creation of the
no-code-test Technician license. There's a copy available for
free download on the NCI website. Over 16 years ago the FCC
said outright that it didn't think the manual morse code test
suited their purpose in granting an amateur radio license.
The FCC said the same thing in last year's NPRM.

I DO have to remind you that the FCC's only job is to REGULATE
all civil radio in the USA. Their only task is to do that and
mitigate matters of interference with other radio services
(plus wireline but that's not concerning amateurs). Theirs
is not to brainwash hams...that's the ARRL's task.

>> Can you give me valid reasons as to what useful purpose in today's age
>> they serve?

[stand by for the LITANY from the Church of St. Hiram]

>Every piece of knowledge has its uses. The difficult part is winnowing
>through it and decide what should be tested and what should not.

Ahem, to olde-tyme morsepersons, manual morse code skill MUST
be tested for any radio privileges below 30 MHz. That's
engraved in everlasting marble and protected by nuclear-blast
armor plate.

>Here's why I think code should still be tested:
>1. It is still one of the basic building blocks of ham radio.

Horsepucky. It was only the first mode used...had to be
in the primitive-technology of early radio using "spark."
Spark is outlawed now, Dee.

> For example,
>one of the "hot" digital modes is PSK31. The developer drew upon personal
>experience and incorporated features derived from that mode to make a robust
>digital mode.

More sinning-by-omission, Dee. Peter Martinez, G3PLX, innovated
PSK31. Using the available Information Theory rules he knew
about, derived from commercial and military technology. It was
field-tested for years in Europe by many amateurs there before
it got any publicity over here. "Hot" is over a decade OLD,
Dee. In 1974 Peter was doing great things with polyphase
networks for voice SSB...it was written up in RSGB's member-
ship magazine. I doubt the ARRL bothered with publicizing it.

>2. Because it is not "book learning", too many people will avoid it since
>it is different than the type of learning they are accustomed to. They will
>falsely think it is hard when in reality it is different. Requiring them to
>learn it gets them over that resistance hump.

So...morsemanship really IS a barrier. You admit it.

>3. Each and every mode has its strong points and weak points. Each of us
>that participate in ham radio should attempt to gain personal experience in
>those modes so that we know by that personal experience what those strengths
>and weaknesses are.

Oh my, there we go on the lecture circuit again.

Dee, I started out working as an Illustrator. That's an artist
who draws/paints things as they really are. I have an aptitude
for that. It is as natural to me to draw, fairly well I might
add, as a physically-endowed athlete is to sports or another
with a musical aptitude is to playing an instrument. The ability
to "advance" in manual morse code skill is NOT a "natural" one
but an aptitude in only a few of us. The US military even
tested for that aptitude in all recruits of the 1940s and
1950s. [I got okay marks in that, by the way...:-)]

The first radio operators used manual morse code. First, it was
fine for the primitive state of the art. Second, it was a mature
mode in the wireline communications, a technology even more
primitive than radio of that time. Telegraphers weren't taken
off the street...they either had the aptitude or they didn't.
Once "radio" got going, the telegraphers (downsized from
wireline comms by those new-fangled teleprinter thingies) made
much of their "abilities" using on-off-keying manual morse. The
Morse Mythos was born and grew like wildfire. Good, good
newsprint copy!

But, as time progressed there came NEW modes, much faster and
more accurate, without need of morse specialists at each end
of a circuit. The radio telegraphers were downsized. They
retired and turned to amateur radio of pre-WW2 times. Morse
was still king of the modes and ARRL (by the 1930s) was

hailing the king as the "best" for all amateurs. None of this newfangled thing called "voice" for them although they did pay lip-service to it. By 1940 the ARRL was King of the membership organizations (through their publications) and they maintained that morsemanship was the epitome of amateur comms. They kept that up after WW2 and on into the single-channel SSB start in the 1950s...again paying lip-service to this newfangled SSB. And you know what? ARRL is STILL trying to promote morsemanship even if sinning-by omission once more.

Back before WRC-03 (that's over three years ago) the IARU took a position that the amateur radio license tests for morse ability was NOT mandatory...make it an option for each administration. Lots of folks went along with that, but NOT the ARRL. League was almost vehement in opposition. OK, the ITU-R amateur radio regulations were CHANGED, going along the lines of the IARU position. [that's the International Amateur Radio Union, Dee] Ah, but NOW the ARRL takes a neutral position, won't go either way...they just say that all amateurs must obey the law...but they lobbied last year to keep SOME manual morse testing for the under-30-MHz privileges. 92 years after being formed, the ARRL just can't give up and change to what OTHER folks want...

>If you are interested, I could construct various scenarios where mode X is
>the best mode.

"X-Files" was cancelled, Dee. [cousin Gillian got a vacation]

>However, unless you specifically want to know, I won't
>clutter up the newsgroup at this time with discussions that have been
>repeated many times by many people already.

Please, go on, Dee. I want to hear from your vast experience in radio and all your guru-like knowledge of what is "best" for radio amateurs. Especially WHY everyone has to emulate the olde-tyme amateur days, the ones before you were born.

I have a wide angle lens (low gain) it`s known as a discone !!!
freq range to 3000megs, supposedly 0db ref dipole that has heard one
or two weak signals just outside its range....now i need a telephoto lens
to make out what it is.......a wideband antenna with gain -- a log
periodic!!!!

With respect Richard, i have a scanning radio receiver that scans up to
2500megs
- that`s a lot of coverage which requires more gain the higher you go....a
discone
just doesn`t cut it gainwise so i need a wideband antenna with more
directional
gain to work alongside the discone...a yagi with one meg bandwidth isn`t
much use
either...imagine how many i would have lying around!!! besides, i know how

to
design those..... :-)

> Anyway, simple scaling works. Just research the model of antenna that
> gives you the gain characteristics you want, and scale to your band of

> much, and especially for a receiver, but latitude is not generous.

If i knew how to scale or re-engineer an existing design, i wouldn`t be on
this NG
asking how to do it ...

Thanks for the advice Richard ......

What if all the wires are not the same length. I know my friends were able
to cover all of 75/80 without retuning but this may have been because of the
losses in the steel wire they were using..

Hi Lee,

Simply because it has a "frequency range to 3000megs" does not mean it
is usable to 3000megs - only that it matches to 3000megs. Matching
and usability are not strictly related.

>supposedly 0db ref dipole that has heard one
>or two weak signals just outside its range

Antennas don't have "ranges." You may experience poor performance due
to the combination of transmit power, path loss, and receiver
sensitivity, but none of this has anything to do with the antenna
(unless its poor construction adds loss). If you have too much path
loss, not enough transmit power, or poor receive sensitivity, then,
yes, a gain antenna will make up for those problems (as long as S+N/N
is sufficient in the end) - but this still does not confer a range
specification to an antenna.

This would be whole lot simpler if you simply told us the model number
of this discone.

>If i knew how to scale or re-engineer an existing design, i wouldn`t be on
>this NG
>asking how to do it ...

You don't offer enough parameters like frequency span, gain, F/B, how
long a feedline, what kind of feedline (lot of potential loss there)
for someone to whip out a design here, and that wouldn't be a modest
enterprise if you did. Scaling is the easiest solution, perhaps you
should buy a log periodic. Google would be another solution, your
problem would not be unique - would it?

From: Dave <W...@comcast.net> on Tues, Aug 29 2006 4:38 pm

>LenAnderson, You have obviously made an INVESTMENT in your
>technical profession.

Yes, I have. Not only has it been intellectually rewarding,
it was also monetarily rewarding...for the last 54 years.

>Make one in your participation in the radio service!!

Kiss my yes, "Dave," I've "participated" in numerous radio
SERVICES of USA civil radio and in DoD contract work from
below LF to Ku-Band. In these previous 54 years I've
communicated from land, from the air, from the ocean
surface...even once "worked" a station ON the moon. Never
once in 53 years was I EVER required to either use or know
on-off-keying manual radiotelegraphy.

>Amateur Radio is a SERVICE!!! If you only think of it as a hobby your
thinking
>is flawed.

"Dave," you are SO FLAWED that you can't think straight.
Here's the real story:

Go to the FULL Title 47, C.F.R., and LOOK at ALL the radio
SERVICES. The word "service" used in Title 47 is a
regulatory term denoting a type and kind of radio activity
being regulated under a Part. Go write the FCC if you
don't believe that. But, you won't believe that since you
are obviously stuck in some kind of "patriotic" pipe-dream
where you think a HOBBY activity is some kind of "national
service."

Look in Part 95, the Personal Radio SERVICES. In there you
will find the Citizens Band Radio SERVICE and the Radio-
Control Radio SERVICE. Those are all SERVICES, "Dave."

There is NOTHING wrong with having a HOBBY. It's a fine
hobby in fact. What is wrong, seriously wrong, with your
(observable) thinking is that US amateur radio is some
kind of quasi-military "national need" that is somehow
"important to the national welfare." It isn't. Amateur
radio is about as "vital to the nation" as CB or some

model airplane flyers on one of the 72 MHz channels.

Yes, HAMS get neat certificates from the federal government (suitable for framing) and like to go around saying "they are 'authorized' by the feds" as if that were some Nobel-laureate accomplishment. It isn't. The FCC is tasked with regulating and mitigating ALL United States civil radio. Since amateur radio transmitters emit RF that requires the FCC to regulate it. The FCC, or rather its predecessors (before 1934), decided that licensing was a way of doing that regulation. To get that license required taking a test. That TEST was never, ever any sort of academic achievement thing (FCC was never chartered to be an academic institution), just something to satisfy the FCC that a license applicant was sufficiently knowledgeable to get that license. Note: Satisfed the FCC...not the ARRL, NOT the nebulous "ham community" or even any "Hams in da Hood."

Have you got that straight yet, "Dave?" Did you take some kind of oath of "service" on getting your amateur license? Raise the right hand and repeat after whoever was prompting you on the oath? No? I didn't think so.

I took a REAL oath on 13 March 1952, "Dave," entering the United States Army. A Real SERVICE, "Dave." I did my "eight" and got an Honorable Discharge. From February 1953 to end of January 1956 I worked HF comms in Big Time radio. You can even download a photo essay of that from this link:

http://sujan.hallikainen.org/BroadcastHistory/uploads/My3Years.pdf

It's 6 MB and will take about 19 minutes download over a POTS dial-up connection. If you look closely at those 20 pages you won't find a single thing about "working CW" (on-off-keying manual telegraphy) yet the whole station ran 24/7 pushing about 220K messages a month. It would be IMPOSSIBLE to send that many (some of which were encrypted) by manual telegraphy unless the signal battalion was doubled. It didn't have to be because the messages got through and on-time. That was 53 to 51 years ago, "Dave."

What do you think the military uses NOW for communications? Data, "Dave," Data. High-speed data, "Dave," not some dinky 1200 baud amateur stuff. DIGITAL. Digital can be on-line encrypted and on-line decrypted securely.

You show me where the REAL Services use manual radiotelegraphy, "Dave." They don't. It is voice and/or data, most of it in the field done DIGITALLY.

>/s/ Dave, BSEE, Program Chief Engineer-retired, LGM-118A(RS), MK21/W87

WTF, "Dave?" So, you tacked on a bunch of undescribed acronym
things supposedly project numbers or IDs. Are we to be
"impressed?" I'm not. I've worked alongside and for PhDs who
didn't bother with IMAGE and all that rank-status-title BS...
WE got the job done, working together.

Amateur radio MIGHT get something done working together. But,
you olde-tymers won't. You have to RULE, holding fast to the
traditions of 50 to 70 years ago...because YOU and all the
olde-tymers had to do it so everyone else has to...and all
you olde-tymer morsemen think that "CW" is somehow "best."
It isn't "best." If you really have a BSEE instead of just
PR BS about morsemanship, you would realize that.

><http://www.strategic-air-command.com/missiles/Peacekeeper/Peacekeeper...>

"Dave," amateur radio isn't about missles. Save your energy
for donating DVDs of "Strategic Air Command" (starring Jimmy
Stewart) to give to impressionable youngsters.

I've been in the smoke-and-fire trade of rocket engines for a
little while (Rocketdyne Division of Rockwell International).
Trust me, rocket engines do NOT use manual radiotelegraphy.
BTW, SAC is GONE, "Dave." A whole reorganization in the USAF
some time ago. No more "oil burner routes" or flying out to
loiter near the USSR (the USSR is gone, too). BTW, there
were SSB transmitters emitting 12 KHz wide RF long before
SAC got the single-channel SSB stuff to use on such
loitering. I know, having to keep a few of those REAL SSB
transmitters running correctly.

Now, "Dave," I can't fault on-off-keying CW any. The key
fob for our 2005 Malibu MAXX uses that. Yes, the last
vestige of high-speed CW (REAL CW) done digitally. Done
by the hundreds of thousands all over the country daily.
Nearly all of them operated by unlicensed NON-MORSE-TESTED
civilians! That Chebbie got in our garage courtesy of
"investments," "Dave." Investments in REAL work, not
playing like big-time 1930s radio ops "jobs" of a long-
past age by AMATEURS.

Dee, the "rules that govern amateur radio" are the ENTIRETY
of Title 47 C.F.R. I don't care that the ARRL pushes ONLY
Part 97. Part 1 has plenty about amateur radio as well as
a few other Parts. Look it up. It's free at the US Government
Printing Office website.

>The section
>on basis and purpose makes it quite clear that their objectives are quite
>different.

The "objectives" of the FCC are to regulate and mitigate ALL
civil radio in the USA, Dee. That's what the Communications
Act of 1934 and the Telecommunications Act of 1996 chartered
them to do (plus quite a bit on wireline comms...which don't
apply to amateur radio).

The "Basis and Purpose" has a lot of POLITICAL boilerplate
in it, just like most of the other Parts for other radio
SERVICES. Get real.

> They want people knowledgeable in ham radio and who are
>interested in expanding that knowledge.

The FCC is mainly interested in all radio services' users
FOLLOWING THE REGULATIONS, Dee. That's their job. The
FCC doesn't "want" people a certain way, only to FOLLOW
THE REGULATIONS.

>> I'm in a pretty technical field, and I study to keep up in that field

"George," you've got a whole bunch in this forum who think
that amateur radio is some kind of veddy formal "JOB" with
absolutes on THE WAY THEY DO IT. It's almost draconian in
the insistence of "correct proceedure." No one will get
fired from that "job" if they don't use "correct" ways but
the way they blabber on you'd think they were "supervisors."

>knowledge, etc are archaic and which should remain as requirements.

Horsepuckey. Dee, "George" is talking about GETTING INTO
amateur radio. Don't give us this olde-tymer morseperson
"I've operated all the modes there are" stuff. Dee, I've
operated lots more modes on radio than YOU are allowed to
as an amateur.

Manual morse code ability IS an ARCHAIC mode of communications
Dee. ALL the other US radio services have either dropped it
for comms or never bothered with it in the first place. ALL.
The ARRL and the olde-tyme morsepersons insist that the manual
morse test "MUST" remain to "show something" about commitment
and dedication. To WHOM, Dee? To YOU? To da Hams in da hood?

>Notice
>that the majority of people advocating ditching requirements are those who
>have not yet passed those requirements, regardless of their age.

Dee, before you get to the downright-bitchy stage, may I remind
you that some of us professionals in radio and electronics
NEVER BOTHERED WITH AN AMATEUR RADIO TEST? I got my First 'Phone
in 1956. Considerably more testing involved than a ham license
test then. Could YOU get a GROL now? Could YOU get a job
working with radio hardware?

>Note that
>the majority of people advocating keeping the requirements have passed them
>and have experience in amateur radio again regardless of their age.

Yes, nine-year-old Extras possess the maturity and wisdom of
the ages, all through having taken that morse test and gotten
that magic certificate (suitable for framing).

>As far as "busy people" go, again refer to the basis and purpose as given
in
>the rules. The government is not concerned about your choice of how you
use
>your time. It has no bearing on what their goals are.

Dee, you are LECTURING again. [just how long have you been
in ANY radio?]

Dee, go look at some 1990 documents on the creation of the
no-code-test Technician license. There's a copy available for
free download on the NCI website. Over 16 years ago the FCC
said outright that it didn't think the manual morse code test
suited their purpose in granting an amateur radio license.
The FCC said the same thing in last year's NPRM.

I DO have to remind you that the FCC's only job is to REGULATE
all civil radio in the USA. Their only task is to do that and
mitigate matters of interference with other radio services
(plus wireline but that's not concerning amateurs). Theirs
is not to brainwash hams...that's the ARRL's task.

>> Can you give me valid reasons as to what useful purpose in today's age
>> they serve?

[stand by for the LITANY from the Church of St. Hiram]

>Every piece of knowledge has its uses. The difficult part is winnowing
>through it and decide what should be tested and what should not.

Ahem, to olde-tyme morsepersons, manual morse code skill MUST
be tested for any radio privileges below 30 MHz. That's
engraved in everlasting marble and protected by nuclear-blast
armor plate.

>Here's why I think code should still be tested:
>1. It is still one of the basic building blocks of ham radio.

Horsepucky. It was only the first mode used...had to be
in the primitive-technology of early radio using "spark."
Spark is outlawed now, Dee.

> For example,
>one of the "hot" digital modes is PSK31. The developer drew upon personal
>experience and incorporated features derived from that mode to make a
robust
>digital mode.

More sinning-by-omission, Dee. Peter Martinez, G3PLX, innovated
PSK31. Using the available Information Theory rules he knew
about, derived from commercial and military technology. It was
field-tested for years in Europe by many amateurs there before
it got any publicity over here. "Hot" is over a decade OLD,
Dee. In 1974 Peter was doing great things with polyphase
networks for voice SSB...it was written up in RSGB's member-
ship magazine. I doubt the ARRL bothered with publicizing it.

>2. Because it is not "book learning", too many people will avoid it since
>it is different than the type of learning they are accustomed to. They
will
>falsely think it is hard when in reality it is different. Requiring them
to
>learn it gets them over that resistance hump.

So...morsemanship really IS a barrier. You admit it.

>3. Each and every mode has its strong points and weak points. Each of us
>that participate in ham radio should attempt to gain personal experience in
>those modes so that we know by that personal experience what those
strengths
>and weaknesses are.

Oh my, there we go on the lecture circuit again.

Dee, I started out working as an Illustrator. That's an artist
who draws/paints things as they really are. I have an aptitude
for that. It is as natural to me to draw, fairly well I might
add, as a physically-endowed athlete is to sports or another
with a musical aptitude is to playing an instrument. The ability
to "advance" in manual morse code skill is NOT a "natural" one
but an aptitude in only a few of us. The US military even
tested for that aptitude in all recruits of the 1940s and
1950s. [I got okay marks in that, by the way...:-)]

The first radio operators used manual morse code. First, it was
fine for the primitive state of the art. Second, it was a mature
mode in the wireline communications, a technology even more
primitive than radio of that time. Telegraphers weren't taken
off the street...they either had the aptitude or they didn't.

Once "radio" got going, the telegraphers (downsized from wireline comms by those new-fangled teleprinter thingies) made much of their "abilities" using on-off-keying manual morse. The Morse Mythos was born and grew like wildfire. Good, good newsprint copy!

But, as time progressed there came NEW modes, much faster and more accurate, without need of morse specialists at each end of a circuit. The radio telegraphers were downsized. They retired and turned to amateur radio of pre-WW2 times. Morse was still king of the modes and ARRL (by the 1930s) was hailing the king as the "best" for all amateurs. None of this newfangled thing called "voice" for them although they did pay lip-service to it. By 1940 the ARRL was King of the membership organizations (through their publications) and they maintained that morsemanship was the epitome of amateur comms. They kept that up after WW2 and on into the single-channel SSB start in the 1950s...again paying lip-service to this newfangled SSB. And you know what? ARRL is STILL trying to promote morsemanship even if sinning-by omission once more.

Back before WRC-03 (that's over three years ago) the IARU took a position that the amateur radio license tests for morse ability was NOT mandatory...make it an option for each administration. Lots of folks went along with that, but NOT the ARRL. League was almost vehement in opposition. OK, the ITU-R amateur radio regulations were CHANGED, going along the lines of the IARU position. [that's the International Amateur Radio Union, Dee] Ah, but NOW the ARRL takes a neutral position, won't go either way...they just say that all amateurs must obey the law...but they lobbied last year to keep SOME manual morse testing for the under-30-MHz privileges. 92 years after being formed, the ARRL just can't give up and change to what OTHER folks want...

>If you are interested, I could construct various scenarios where mode X is
>the best mode.

"X-Files" was cancelled, Dee. [cousin Gillian got a vacation]

>However, unless you specifically want to know, I won't
>clutter up the newsgroup at this time with discussions that have been
>repeated many times by many people already.

Please, go on, Dee. I want to hear from your vast experience in radio and all your guru-like knowledge of what is "best" for radio amateurs. Especially WHY everyone has to emulate the olde-tyme amateur days, the ones before you were born.

Beep, beep,

Scanners are notorious for a lack of front end selectivity and
resultant high intermodulation products / noise.

Sometimes they depend on narrow band antennas to supplement their
meagre front end selectivity.

In the absense of external front end selectivity, you may find that
the realisable sensitivity is quite a deal higher (tens of dB worse)
than specification, depending on your own RF environment.

Yes i am taking a bit of a chance with a wideband antenna Owen but
if i can resolve a signal, it is a start.....i have built a bow tie
can-tenna
for 23cms which seems to work okay, now, i`ll build one for 13 cms
with a corner reflector, only because i know something is there!!!.

> Sometimes they depend on narrow band antennas to supplement their

Agreed!!.

> In the absense of external front end selectivity, you may find that
> the realisable sensitivity is quite a deal higher (tens of dB worse)
> than specification, depending on your own RF environment.

That is where i will need a narrow filter pre-amp which will be bought (or
built)
when needed.....

Thanks for your input Owen, the Yaesu is certainly a great deal better than
the
AOR 2002 which is as wide as a barn door, but served its purpose!!!.....

Regards..

3290. Ground screen material

Newsgroup: rec.radio.amateur.antenna

I have a vertical antenna I would like to build a ground screen for.
Can someone suggest what type of material I can use for this?
I would like to purchase the material from Lowe's or Home Depot if
possible.

there is no ethics involved here.

now a true ethical question:
can an unlicensed person using radio technology to violate part 15 still
be in violation if he had a ham license (we're talking about using 802.11A
at full power for a 10 mile shot folks!).

With the tons and tons of sour grapes from these Morse Forever folks,
no one has won anything.

3294. light HF beam (not wired) ?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-08-30 11:51:27 UTC
From: Thierry
Message-ID: <44f57bc1$1@news.vo.lu>
Source record: 53531

Hi,

I have already checked and I come back without the answer so maybe that some of you could help me...

Does it exist manufacturers of very light HF beams, using light and quite resistant material instead on steel or aluminium, the purpose being to use it on portable ops, in the field, on vacations or to install it for a week-end or a very light mast.

I don't speak of wired beam like hexabeam and others quad that require a lot of time to be assembled and that are fragile, but standard 3 ele made of light material (and I don't speak of bamboo, HI!)
There is well titanium but there are very expensive (see titanex)...

Do you know any other very light material used to made HF beams, and some URL of manufacturers ?

Thanks in advance

Thierry

EMT conduit is NOT made from aluminum but galvanized coated steel. It comes
in different sizes but they are not a tight fit from one size to the other.
It would possibly last 3 years if you are not too close to salt water.

Your rudeness is clearly expressed in your one word response [above].

A more appropriate response, carrying the same meaning, but suitable for an open list, would be 'bovine defacation'!

No wonder Ham Radio is going the way of CB with people who express themselves so poorly and are unwilling to work for something they value.

Where your treasure is ... there your heart is!

ARRL Antenna Handbook gives all the LPDA design equations.

However, LPDAs do not have high gain!! They have typical gain of 6 to 8 [+/-] dBd and broad bandwidth. They typically function as either a three or four element driven array. They are driven arrays, not parasitic [i.e. Yagi principle] designs.

Also, LPDAs for 3,000 MHz will have a L/D ratio issues with element geometry and general construction will require fairly precise measurements.

Unlike a Yagi, a long boom length LPDA does not equate into higher gain.

Best bet is aluminum porch screen... Lay it down in a square under the antenna... Attach radial wires and carry them out as far as you can... You can also get aluminum roof flashing in several widths... I used this for my 160 and 80 meter radial experiments last summer... I have several rolls of 24" wide on the shelf right now waiting for the next burst of antenna testing...

Dave, he can't help it, his education is "limited" and doesn't know any
better - due to NO EFFORT - effort as he said was bull shit too. So you
can't expect much out of someone who has apparently made effort - to do
something.

Mork the dork - The man is right - IT IS AN INVESTMENT - OR shall we assume
your radios were given to you by the welfare office, paid for by pan
handling on the street, or some other way which YOU didn't have to pay for
them? ALSO - to get involved in such a hobby - ANY hobby - YOU MAKE AN
INVESTMENT in time and well - whatever to enjoy it. We won't go with effort
since it too is bull shit.

Titanex is a German company. They make beams out of a Titanium-aluminum
alloy. Light but not cheap. Word is they may not be a great supplier /
vendor...at least not to the US. Their US distributor cancelled their
contract.

Dave Said:

>I'll say it again ... INVESTMENT!!

>If an activity is to have value it must have INVESTMENT.

Hi Dave,

Thanks for the replies, I surely didn't mean to get a flamewar going, but, it seems there are some very
strong views on this.

I don't mind putting an investment into something...usually when I learn something new, I research and get
into it 110%. The trouble with the requirements and all there that I see is, that it puts up a very high
initial investment before you can actually get in and do anything with it. I guess I question, well how do I
know it will be worth all the time invested before I even get to 'play'?

In my case, and I'm sure many others out there in this day in age, my TIME is what is of such short supply. I
have no problem laying out cash for equipment...with most things I do, I generally jump in with both feet,
buy equipment and 'learn as I go'. I'd like to do the same with ham and other radio technologies, but, in
this case, I find a large wall in front of me of study and test taking, before I even get to jump on the air
even once to see how much I'd like it.

Does that make sense to you?

Thanks for the replies,

noonespecial

Most hammies I've met at hamfests and other venues would
likely blast-away with wincing faces and shi+-eating grins even
if the Queen of England was present in the room. Hams, for
the most part, have no class, poor social behavioural skills and
in general dress like bag ladies.

Wanna see a ham farting video???

Hi Lloyd,

Thanks for the reply. Can you explain what SSB is to me, or post some informative links? I've seen ssb
(single side band?) in the same breath/post as some CB radios. I'm not sure what it is, or what special
equipment it takes. About all the info I can google points to radio communications at sea.

Can you use this on land? License and equipment requirements?

Thanks in advance for any info or pointers, I'm trying to learn about all this differences in publicly
accessible radio.

For a 10GHz vertical an aluminum pie tin should suffice.

Yes thanks Dave i am aware of the functions of a LPA i just need a little
directivity
and a little more gain than a discone offers, plus design software!!...

There is also such a thing as aluminum electrical conduit. I am using an 8 foot length as an antenna mast that measures about 1-7/8 OD. There is a tribander directly above to rotator, a 6 meter 7 element beam at the top, and a 2 meter 10 element in the middle. It has been up 7 or 8 years, gone through high winds, and has shown no signs of bending or corrosion. It is fairly soft, but has thick walls; still, a lot lighter than steel.

Let it out in morse code! People will look around to
see which radio it's coming from and you'll remain
undetected.

Hi Lee,

Because of various clues in your discussion, and your claim
>>If i knew how to scale or re-engineer an existing design, i wouldn`t be on
>>this NG
>>asking how to do it ...
Re-engineering goes to the heart of a successful outcome and is part
and parcel to modeling. On the other hand, the trivial work for
simple scaling will always give a solution.

EZNEC, although probably the best modeler for the occasion, is one
that does require deep knowledge of design elements and program
operation in this case. Modeling an LPDA is not trivial.

I didn't look up any rules or sections of law anywhere, so I guess I'm answering a question blindly. I'm in Canada, but I felt compelled to answer even if I misunderstood the question.

I believe that government has written into law that a licensed ham should only use the power, or enough power required or necessary to communicate. Ten miles down the road is not a really great distance, contrary to what some CBers think, so maybe you could still use smoke signals to communicate unless you are then violating pollution-control laws, and or harming the tree environment/ecology system of the area by burning code into the sky.

I think that this part of the law still stands in Canada....that one should only use enough power to communicate whether it be an emergency or not.

If I missed your intention by 10 miles, please ignore this post. Thanks,

Jack

> of the circulator is unterminated

You should think about it because amateur radios don't usually have circulators on their output, and the result illuminates a corner of the discussion that you've been pretty closed minded about.

Without a load on the circulator, you must know that no energy can be flowing to it or through it. No power is being dissipated by it. What effect should that have on the total energy in the transmission line, and why?

I hope it's not true about Reg. That would be a huge loss. Perhaps somebody will archive his website.

Example.

A few months ago a group of ham radio operators went into the central Pacific Ocean to an island named Swain's Island [ATOLL]. Swain's Island had just been approved by the Ham radio Certificate Powers {American Radio relay League] as a separate DX [distance] entity and as such it qualifies as an entry into the various DX awards [DXCC being the prime award}. [DXCC means you have submitted written proof of confirmed contacts with other ham radio operators in 100 or more other countries [or entities].

The Hams operated from this rare location for about a week and then returned home. There is no-one there today!

Let me digress into another of your questions: i.e. What is SSB?

Fifty years ago ham radio, and still today the AM broadcast band, transmitted three components to put a signal on the air. First, was the carrier that set the dial frequency e.g. 3950 KHz. The carrier contains NO information, it just sets the dial frequency. Then voice audio was added to the carrier. This addition [modulation] produced two audio signals around the carrier. One above the carrier, the other below the carrier. So, the resulting signal had the carrier and one upper side band and one lower sideband. The carrier contained 2X the power of the audio. And the audio was redundant with 1/2 the audio power in each sideband. The resulting signal can be described as Double Sideband Plus Carrier.

In the 50s and early 60s design techniques were incorporated to suppress the carrier, which contained NO information; and to eliminate one of the redundant sidebands. The resulting signal is Single Sideband [one audio channel] with suppressed carrier. [SSB = Single Side Band]

In lieu of any other meaningful test (and there currently is none), it
shows a willingness to put in a minimum amount of effort.

>But, given that many professional people like myself are stretched for time, what good does all the licensing
>and code requirements do for you besides build up boundries to doing something new and fun?

You might ask that about anything. Given that <insert group here>
like myself are stretched for time, what do all the requirements for
<insert something here> do for anyone?

>I'm in a pretty technical field, and I study to keep up in that field everyday, the last thing I want to do,
>is have to spend my weekends studying to talk on a radio.

So don't. Buy a CB, FRS or GMRS radio and talk all you like. Those
are the services created for folks who just want to talk on the radio.

>If less stringent requirements were there, I could
>easily afford the tools of the trade, and would like to just jump in and start working with a ham setup. I'm
>particularly interested in exploring the amateur radio/computer connections.

You won't like that - you'll have to devote a lot of your precious
time to learning things - electronics, both theoretical and practical,
programming, reading a waterfall display, keeping your signal
distortion-free ...

You can't just plug a radio into a computer and start using them.
Digital communications doesn't work if you do it that way.

>Can you give me valid reasons as to what useful purpose in today's age they serve?

No, since someone who wants instant gratification can't be bothered to
listen to why that's the wrong way to do something. Your time is

probably much to valuable to spend it learning enough to understand why you can't learn enough in an instant.

Go memorize some test answers, get a code-free tech, hook your computer up to your radio and, in 6 months, you'll have your radio up for sale on eBay, because "it doesn't really work".

Bummer.. well, there's a bunch of ways to test, flashing lights and other
ways. If dyslexia is a problem, just have to get someone to read off the
dit-dah sequences while you memorize them, or use a recorded audio lesson.
There's always a way!
gud luck,
rb

A GMRS license costs money. A ham license costs study (time). Your
choice. Either one lets you "talk on the radio".

>
>Can you use this on land? License and equipment requirements?

It's a mode, like CW or FM. It's actually AM, with the carrier and
one sideband chopped off (or never generated). No whistles, the same
transmitter can handle more power, it punches through noise and
interference better and, if you have a quadrature detector (sorry,
Usenet isn't large enough to explain that in a post - you'll have to
learn a little engineering), it's almost as good, for getting through,
as digital or CW.

You can use it anywhere you can use AM (as far as ham and CB
frequencies are concerned, anyway). Same license as any AM voice mode
for the frequency. SSB transmitter. Receiver has to at least have a
beat oscillator (BFO), but a SSB receiver is better.

then there is the problem of getting the VE to even discuss acomdation
where I lived before they would not speak to me with a Doctor (md)
dispite the fact the PHD's and MSW tend to dianose Dyslexia, then they
want seris of test result and your medical records truned over the the
ARRL all fo them for evaluation by NON medial people indeed we saw
last year our own Steve Robeson making fun of the facts I was looking
for the min osrt of testing that an MD could prescribe to dianose
dyslexia

he has tormented me ever since for daring to try accomation

there indeed was a way but I was too honest to take since I got to the
point where in some sessions I could sending, other session receiving,
it was offered long ago when I was first trying that someone would
simply scamble 2 session together and say I passed them both on the
same day instead of 2 weeks apart as was realy case (btw getting to
the stage where passing iether way was 1 in 4 coccourance took 4 years
working 35 minute 5 day per week, and suffering through spliting
headaches. It might be possible now but it aint worth it the FCC will
act soon enough

Here's another:

""SOMALIA, THE BLACK HOLE OF ANARCHY

BY AHMED Q. BURSALIID

In mid July 2005 The U.S. intelligence agents, working with local warlords, have carried out counter terrorist operations to seize sus&#65533;pects. "Somalia remains the theatre for a shadowy confrontation involving local Ji&#65533;hadis, foreign Al Qaeda operatives and in&#65533;telligence services from a number of re&#65533;gional and Western countries," says a report by the International Crisis Group in 2005. The report says the "dirty war be&#65533;tween terrorists and counter-terrorist oper&#65533;atives in Mogadishu appears to have en&#65533;tered a new and more vicious stage that threatens to push the country further towards Jihadism and extremist violence un&#65533;less its root causes are properly addressed."

The Somali transitional federal government was formed in neighbouring Kenya in 2004 and moved into Somalia June 2005. However, the administration has failed to relocate to Mogadishu, the Somali capital, because the city was considered unsafe. Due to the insecurity of Mogadishu, the TFG relocated to Jawhar, which it later decided to move to Baidoa.

Warlords and leaders of Islamic courts have been fighting in Mogadishu for about five months. This led to the loss of hundreds of civilians and
destruction of properties. Somalia, which had been in a state of anarchy
for more than a decade, has once again gone to war; this war was somehow
different from previous ones. The nature of this war is seen to have some religious and political clash while previous ones were much related
to tribal and feudal conflicts. Each one of the conflicting parties is claiming that the other group is related to Al-Qaeda when the reality is
somehow different from that. After months of armed conflicts within the capital city of Somalia, Union of Islamic Courts took the lead with enormous points by eliminating the warlords who took hostage the country
and its people for 16 years.

United States of America, which earlier denied any allegation of helping
or giving hand to the warlords in the fight to weed out the Islamic Militia in Somalia shortly after the takeover admitted that it had been supporting warlords to destabilise the Islamic militia. America has been
an active player in the politics of Somalia, and until now its policy towards restoring peace and stability in the war -torn Somalia is somehow obscure.

Somalis believe that it is the right time to take advantage to restore the lost hope of good governance in the country as Union of Islamic Courts led by Sheikh Sharif imposed law and order on Mogadishu, which was seen neither for 16 years. Hundreds of families from overseas

countries returned back to Mogadishu, the capital city of Somalia since the takeover took place.

At first Transitional Federal Government welcomed the political change, which took place in Mogadishu as the Union of Islamic Courts disarmed a pack of US-backed warlords that took the country and its people hostage for more than a decade. But soon after the Islamic Militia started to capture some other cities, the TFG warned the Union of Islamic Courts of
capturing farther cities. A big gap of political misunderstanding came in between the Transitional Federal Government and the Union of Islamic Courts, after the president of fragile Transitional Federal Government requested peacekeeping forces from the African Union. As the new Somali constitution inked in Kenya says, "Peacekeeping forces should not come from the neighbouring countries (Ethiopia, Kenya and Djibouti)". Likewise, the parliament passed a motion, which it was requesting peacekeeping troops to Somalia without paying attention to the classification of peacekeeping forces from AU countries and of front
line countries. This has created an escalation of political crisis in Somalia. Ethiopia, which is the common enemy of Somalia has sent its troops to Somalia in an attempt to protect the Transitional Federal Government.

This time, Arab League took the political platform of Somalia to mediate
the two conflicting parties. TFG and UIC were invited to attend a mediation conference held on June 2006 in Sudan to settle their differences. After a reconciliation conference, presided over by Sudanese president Omar Hassan Albashir, the current chairman of Arab League, the reconciliation process derailed with unknown reasons but it is believed that Ethiopia was the main figure, which made the reconciliation process fail as the outcome of the meeting could not meet
the criteria of Ethiopia's plan to Somalia and then, President Abdullahi Yusuf Ahmed, a well-known pro-Ethiopian warlord and his loyal prime minister Ali Mohamed Gedi, a vet scientist started to advocate the
legality of Ethiopian Army presence in Somalia.

The Somalis are of the opinion that the involvement of Ethiopian Army in
the peacekeeping operations in Somalia could cause havoc and deterioration of the political condition of the country in any case as Ethiopia is an old aged enemy of Somalia in East Africa. While a vast majority of the Somali public strongly opposed to deployment of Ethiopian troop into Somalia under any pretext, president Yusuf's political stance towards the deployment of Ethiopian troops in Somalia is clear and also in action by denying the presence of Ethiopian troops in Somalia just to protect his presidential seat.

Since the reconciliation conference in Sudan derailed a number of ministers resigned due to the political misunderstanding between TFG and
UIC. Prime minister declared that he would be nominating successors of the resigned 24 ministers. In addition to that, the prime minister himself survived after the Somali parliament passed a motion of no confidence against him recently.

Moreover, Prime minister of Ethiopia Milez zanawi whose government earlier denied any presence of Ethiopian troops in Somalia told BBC that
his government has sent troops to Somalia to protect the Transitional Federal Government from the Union of Islamic Courts. While on the other hand, Eritrea is also believed to be an active supporter for the Union of Islamic Courts. Somalis believe that the support from both Ethiopia and Eritrea respectively is much related to a proxy war in between them.
US government warned Ethiopia and Eritrea stop the proxy war they are playing in the Somali territory.

I know what happens if the circulator is not present. I
just don't don't know what happens with an unterminated
circulator.

Maybe you can help me out here. If the load resistors
are removed from the circulators in the previous experiment,
what is the forward power and reflected power readings on
the one second long lossless transmission line during
steady-state?

> Without a load on the circulator, you must know that no energy can be
> flowing to it or through it. No power is being dissipated by it. What
> effect should that have on the total energy in the transmission line,
> and why?

Let's remove the circulators and try to figure out what
happens. Let's assume the signal generator is a Thevenin
equivalent with an internal resistance of 50 ohms and not
equipped with a circulator.

200W SG---one second long 50 ohm lossless feedline---100W SG

Would you agree with me that during the first second, the
feedline is loaded with 300 joules because there have been
no reflections? What happens after that depends upon the
reflection coefficients at the signal generators. But the
$64k question is what happens to the original 300 joules?

> I hope it's not true about Reg. That would be a huge loss. Perhaps
> somebody will archive his website.

One of the posters to the news
of Reg's death was peteredw@blueyonder.co.uk whom I suspect is
Reg's son (or nephew). Humans are mortal and can die at any time.
My son died when he was 8 months old. I wish he had lived as long
as Reg who certainly had a full, useful, and colorful life.

Hi Walt,

The paths are tied intimately to my file system hierarchy (which is
pretty deep). Rather, I will give you a walk-thru. In spite of the
apparent complexity (it is a technician's tool), it is quite simple to
use with only two or three particulars to satisfy:
1. As directed on the front page, press the NEXT button;
2. On the next page for Project Name, enter Reg Edwards G4FGQ;
3. Below that (skip the category), click the ellipses button to open
a storage path and select an existing folder the website will be
stored here in a folder named Reg Edwards G4FGQ;
4. Press the NEXT button at the bottom;
5. leave the ACTION selection at "Download web site(s)";

6. past Reggie's top level page,
http://www.btinternet.com/~g4fgq.regp, into the Web Addresses text box;
7. Press the NEXT button at the bottom;
8. At the next page, Press the FINISH button at the bottom.

This will start the robots harvesting with a view of them on a new page that shows each robot in its own thread - about half a dozen of them running simultaneously. Depending on the load at the server, the entire process should take 5 minutes or so at T1 speeds. The total download is 4.33MB.

The robot activity screen will disappear at the end of the harvesting.

I can zip up a copy (sorry Reg) and mail it for those who want a copy that is located at the drive root (I did this down load again to confirm the steps described above).

This is a terrible shock. Please accept my condolences.

Sometimes the measure of a human life is the size of the empty space
that's left behind. We're going to miss some first-class arguments in
future; and above all, we're going to miss the man.

For Linux and other Unix-type-system users, a simple

wget -r http://www.btinternet.com/~g4fgq.regp/

will grab everything, and fix all of the links in the .html files
to be page-relative so that the mirrored copy is self-consistent.

Richard,thanks for the walk-thru outline, but none of the pages that come up
with the url above have a 'next' button. Apparently, a different page comes up
when you access the url. Any suggestions?

Walt

The problem may be due to too quickly writing up the instructions, All
instructions are specific to HTTRACK operations, note ammendments:

Hi Walt,

The url was for cut and paste into HTTRACK's text window. This is for
the robots to use as their top level address to drill-down into the
website. No browsers need be open to perform this.

If that were the case, I would design an olfactory DSP to be worn at all
times in public. IT would be tuned to "rose"

If you're looking for software to design an antenna for you, EZNEC isn't it. EZNEC will analyze an antenna you design, but it won't design it for you.

The carrier is just there for setting a dial frequency? How about if
one just transmitted ONE component, the carrier and then turned it on
and off and regular intervals. It might be possible to use the on/off
pulses to convey information, huh?

> In the 50s and early 60s design techniques were incorporated to suppress

Those "design techniques" were used as early as about 1927.

Where is all this going?

Pete

Before it was a four/six SteppIR, it was a three/five. I am one of the early customers and upgraded the beam when I finally got around to the tower. These guys make a great product and they support it aggressively. No quibbling about warranty coverage BS, you talk to the founders.
A great product.
73
H.
NQ5H

PS
If you have high winds, and the antenna loses an element, and you had the copper tape retracted, it's $20 for a new fiberglass tube.

I can think of a couple of solutions to your problem but as a personal
favour to you I will not do anything to help you break the law and from
what I have seen so far no one else on the group wants to see you do
something that you might regret if you ever get caught.

The time investment is not as much as it seems. That is even more true of
someone who has experience in related fields or has experience in the art of
studying. For those with some existing experience in related fields, they
can often read up enough in a single weekend to pass the Technician written.
This will let you get your feet wet in the VHF/UHF and higher frequencies.
There's quite a lot that can be done in this area if you invest in the

equipment.

Again if you have some related background, the General written is not particularly time consuming to study for either. The code is only as hard as you make it by fighting yourself. If you decide that you will learn it, the average person only needs about 30 hours to get to 5wpm, assuming that a good training method is used.

Getting the General license gives you all modes and all bands and the maximum power privileges. The only thing you do not get are some subsections on some of the bands that are reserved for Extra licensees.

Now the Extra test is quite a bit more difficult but is not required unless you want to get into those subsections mentioned above.

You spoke of "learning as you go". Basically ham radio is the same. Even the Extra class license has only scratched the surface of all that might be involved in amateur radio. The tests & licensing are to insure that you know enough not to get hurt, not to cause harm to other people, and not to make a mess on the bands. Also they are to insure that you have a grounding in the basics so you don't go spinning your wheels trying to get things working.

You might ask why this is important. Let's just address the safety area for a moment. Well for example, you can actually get a burn from grabbing an antenna that is being used to transmit. If you get into microwave transmissions, you could fry your eyes (or somebody else's) if you look into the end of a wave guide while it's being used to transmit. You can get electrical shocks from feedback due to a poorly set up station. This is just a small sample of some of the things that you should be familiar with.

the investment s not the same for different folks it can't be so the
e;lcetircal engineer less of a ham for making a lessor investment?
that is the clear inplacation

indeed you have implied that My Wife is a more cabble member of the
Tech the class because she had to wrok MUCH harder than me to get that
license

This is some of the very information that you will learn in studying for a license but here's the nickel tour.

An AM signal (like the radio stations use) has a center carrier frequency. This is modulated by the information (voice, music, etc). The result of this modulation is that two sidebands develop that are identical but are mirrored about the carrier frequency. All the information is carried in the side bands and both sidebands carry the same information. So the smart boys got to thinking and asked why do they actually need to transmit both sidebands (since they contain the same information) and why do they need to transmit the center carrier (which contains no information). They developed a way to eliminate the carrier and one of the side bands on the transmit end and a method to receive and convert it to useful sound at the receive end. This is called (ta-dah) Single Side Band. The main advantage of SSB over AM is that the transmitted signal is much narrower so more stations can fit in the same band width. An additional benefit is that because the signal is narrower, you can use a narrower filter and so reduce the amount of background noise receive with the signal. Since the carrier and one side

band are eliminated before the signal power is boosted for transmission, you also end up with a stronger signal because the power is, in essence, focused on boosting a much narrower signal. For example, my radio gives me 100 watts out on SSB but only 25 watts out on AM.

Amateur radio operators use SSB as the commonest voice mode on HF (shortwave communications). Some hobbyists do use AM from time to time partly because they enjoy it and partly because of its historical significance. There is also SSB activity (as well as some AM) in the VHF and higher frequencies. Basically, in the amateur bands, it is legal anywhere that voice communications are legal. However in VHF and higher frequencies, there are band plans that one should follow on where to use SSB.

As far as equipment goes, you've got to read the specs. Some CBs (an unlicensed radio service) have SSB as well as AM. For amateur radio (a licensed service) HF voice transceivers, SSB is normally the standard mode with AM being an option that is available in most radios.

DX simply means distance. If you are talking about HF transmissions, it
normally refers to countries outside your own. If you are talking about VHF
and higher, it can be within your own country but at distances beyond line
of site communications.

The "DX community" is simply a term that refers collectively to those who
are particularly interested and involved in the longer distance radio
contacts.

I would like to add that DXing isn't limited to chasing awards. Some people
just like to find someone in a foreign country to ragchew with. One day I
was lucky enough to come across a gentleman in Italy who simply wanted to
talk not run a pileup. We spent about 1/2 an hour just chatting.

I would like a complete copy of the G4FGQ site. There is still much I
can learn from Reg.

I believe we have run the HTTRACK site over bandwidth already. I am
afraid if we all try to download a copy from Reg's site we will over
run it as well. I can also pass it along or place it up as a down load
on my site.

I will miss Reg.

Richard, we just returned from eating out, the reason for the delay in continuing the attempt to download Reg's web page. Anyway, using the url you gave I cannot find any page to enter Reg's web address for downloading, also no place for entering a Project Name. Are you getting a different screen than I with that url? What am I doing wrong?

Walt

Richard, the various screens that come up using the url you gave are totally unfriendly to a user trying to enter anything to start a download. Like other programs, they say 'you can do this...,etc,' but they allow no entry. Am I using an incorrect url?

Walt are you running the program called Httrack ? This is a special program
that lets you download a web site to your computer so you can look at it at
any time or do other things with it. I think it is a free download. Just
do a Google search for it.

YOu start the program. Then click near the bottom where it says NEXT.
Type in anything for the project name. Click next. In the blank white spece
under where it says Web Address:(URL) type in the web address you want to
download. In this case http://www.btinternet.com/~g4fgq.regp/
Then NEXT. Then Finish.

From there it should start downloading the web site and place it in the
directory that shows up a few screens back , usually c:\my web sites.

Hi Walt,

I thought you had downloaded the utility HTTRACK, but it sounds like
you were trying to use their website to do the job. No, you first
have to get the tool to go and get Reggie's work:

Go to the download page at:
http://www.httrack.com/page/2/en/index.html
in the column marked "Choose file to download" select the first item
below that heading called "httrack-3.40-2.exe". Run this installer,
start the program, AND THEN follow my instructions already provided.

I'm very sorry to hear this news. On this NG and a few similar technical groups, there are a handful of people whose posts are mandatory reading for me. Mr. Edwards ranked very high in that list. I've also found his technical programs to be useful again and again. That's saying something, considering the wealth of technical programs available on the internet.

His non-technical writings are equally impressive to me. If you haven't read "A Bit About Reg" recently, take another look.

http://www.btinternet.com/~g4fgq.regp/page2.html#S205

This and some similar diversions in newsgroup posts disprove (for me) the stereotype of the technologist as being somehow limited outside his narrow field of expertise.

Here's hoping that wherever he is, the propagation is good, the wine excellent, and the technical discussions lively and spirited.

3386. Need a single antenna solution for an IC-R3 receiver

Newsgroup: rec.radio.amateur.antenna
Date: 2006-08-31 02:33:07 UTC
From: "Bob D." <bobmgtd@insightbb.com>
Message-ID: <EYedndvTerP912vZnZ2dnUVZ_sadnZ2d@insightbb.com>
Source record: 53523

I recently purchased an Icom IC-R3, a handheld 'DC to Light' receiver. It didn't take long to discover that the telescoping whip that came with the unit is worthless at HF and AM broadcast frequencies. (I suppose the 50 ohms input looks like a short circuit to an antenna only a couple feet long at 500 KHz.) I'm thinking of stringing up about 60 ft of wire from the house sloping up to my tower and feeding it directly into the center conductor of some RG58 or Mini8 coax. Would this provide a usable signal for the IC-R3 from say the AM band through 440 MHz? I'm not looking for DX performance, just casual AM broadcast, SWL, and local 2M/440 listening.

the code requirements?
>
>The 'use' is something you just can't understand. The 'use' is a commitment of
>time and talent which adds value to the license. The 'use' is investment.

The term "investment" is very misleading. To explain my position, I am
in agreement that CW testing should go the way of the dinosaurs. I
have no problem with technical testing, as a way to ensure that
potential Hams can operate their radios properly, without causing
interference with neighbors and other Hams world wide. There is also a
safety factor, with transmitters that can kick out a LOT of
potentially dangerous power. So, technical exam = good idea.
Here in Canada, CW is not required IF you achieve at least 80% on your
technical exam. You need at least 55% WITH CW.
http://strategis.ic.gc.ca/epic/internet/insmt-gst.nsf/en/sf08435e.html
This seems fair, to me.

As for the "investment", not all investments are valuable. I invested
years of training to be a fully qualified mechanic. There is
considerable value in that investment, obviously, as it is my bread
and butter.

But, would my investment be more valuable if, for example, if an
additional year of carpentry training were required for me to be
certified? I mean, after all, cars had wood frames and bodies at one
time so a mechanic would have needed carpentry skills...back in the
1930's. Such an investment would be a bad one. The skills would have
no value and do nothing to enhance my skills as a mechanic. The extra
investment would have no return with regards to being a mechanic.

Carpentry would not make me a better mechanic and would not prove to
the world that I really wanted to be a mechanic.

CW is as useful to todays Hams as carpentry is to a mechanic. A good
thing to learn, and potentially useful, but should not be a barrier.

But then again, a mechanic *might* need to do urgent bodywork on an
1930's wood-bodied ambulance and therefore save somebodys life. ;-)
{hehe...sorry..just had to pour on more coal..}
Just about as likely a scenario as CW being the only way to save a
life.

But then, if I were stranded on a desert island and found some old war
time aircraft wreckage, I could modify a magneto to be a spark
generator and spark out an S.O.S. My mechanical skills help me there.

Well......could happen!!

Perhaps if RS didn't sell so much redundant Sprint Telephones, overpriced
DVD players and TV's and their UTTERLY USELESS junk toys that
start to appear each Labor Day and multiply right up till Xmas, their sales
would rise. Personally however I would not miss them if each and every
RS were to close and the company was to go the way of FW Woolworth.
Most of the stuff you can get at RS you can usually get at Walmart for
50% less price anyway, plus Walmart employees are usually a tad more
intellegent than your average Radio Shack stooge.

I'm not sure I recall all the other posters idea of investment - but
"mine" - was referring to the time/cost how ever little - "spent" or
"Invested" - if you will - in the way of time to study or prepare for the
exam - acquire equipment AND to actually go on the air to make use of it.
So - yes it "can" be looked as an investment - even if in a "minimal" sense
of the word.

IN the way I "think" you're referring to - as an investment towards a
"rewarding career" or leap forward into life - eh - depends on the person.
Many do NOT make electronics their lifes work. BUT, many have started from
ham (some from CB and then ham) and went on into some electronics or
electrical field. So for "them" - it "was" an investment of sorts - into
their future.

Just like another part of this thread where "memory and memorization" was
being used, hacked, slanged - the word "investment" could also go that
direction. It is all in how you want to look at it and perceive it.

Just my 2 cents!

L.

3395. wideband antenna for IC-PCR1500

I'm looking for a discone antenna and have been searching for the AOR model that matches my radio. But ... hey! Where is everybody?

Nobody here. At last I am alone.

That's okay, I'll just use this whole NG as my personal platform. Let's see set up my radio base over there, the antennas up there.

Too bad I don't send and receive; I could get rescued.

Signing off now with my new identity, Robinson Carusoe.

If this is true, it isn't so surprising - a few stores have closed locally. Many are not as busy as they once were and I suspect "might" be going the same way in the near future. "SOME" things are still able to be gotten there that Wal-Mart doesn't supply - BUT - then again - those are the things which "experimenters", "builders", "technicians", "radio enthusiasts" would buy. ALL ELSE - is "Wal-Mart" related type items. Heck - even "Wal-Mart" sells phone plans now for at least a couple companies but they don't hound you when walking in the door to buy one. "IF" Wal-Mart sold "ALL" items that RS handled and "Cheaper" - yeah, I think RS would go DOWN.

Lets not give Wal-Mart TOO much credit here - I hear they're not doing so well all the sudden - either. The local store - ranked one of the top sellers in the nation - parking lot and aisles always full of shoppers, bringing in "millions" a day (data acquired from a good source) - is laying off people, cutting back hours, freezing pay raises, etc. AND I hear that is a trend across the nation in "Wal-Mart". So - even that giant may be coming to it's knees. My question on this issue, is I wonder if it has anything even remotely related to do with the "mexican" hiring policies they were busted on? A retaliation of having to pay "higher" wages to Americans - or shall we say "Legal" residents? They closed a store down in Canada when the people there wanted to form a "union" - so I heard in a news column. Sure makes you wonder. Its amazing what the holder of the wallet can do!

It is interesting (in a sad way) to see these big companies going belly up or at least having woes..... It makes you wonder where we are actually headed. HERE - Wal-Marts ARE one of the biggest employers. If they go out - the unemployment rate will be higher than George Bush Jr. can count. Almost as high as his deficit.
I know Wal-Marts and yes some others too - already gone by the way side - have been accused of killing off the Mom and Pop stores, but the whole picture just plain SUCKS.

I guess the adage applies - it IS a "Dog eat dog" world out there.

L.

Hi Walt,

Some or most of the popular web browsers have a feature where you can use or view the web page offline. Look around in the menu of your web browser to see if you can find such a feature and turn it on. The browser will then store the contents of the web page on your computer so you can view it without going online.

Good luck OM and 73,

Jim AC6XG

Many thanks for all the kind words about Reg. I'm new to newsgroups but have followed avidly dad's two favourite groups over the last 24 hours. (It somehow makes me feel closer to him). I'm especially pleased to read that you are trying to keep dad's website alive (cheers for that) and also the postings from those who say they are still learning from his programs. Dad was definitely all for education and it would have warmed the cockles of his heart to have read such postings. (Somehow, I think he is reading them and will be watching you from afar). My brother Pete is the one to do all the technical 'stuff' in preserving the website, My "technical"experience concerning antenna only extends to remembering to remove the aerial before entering the car wash! TTFN Jean Proctor.(Reg's proud daughter)

3404. the Inside of the loop antenna.....?

Hi Guys,
I have had a 80m loop antenna,up at 30ft.;in my backyard for over 4 years. It works great.
Tunable on many bands except 160. I suppose I could short the leads together to get 160m but I don't do that. Which brings me to this question: I have a COBRA ultra-lite senior which
is an inverted "V". The feedpoint is at 55ft.,and the ends are at say 15ft. above ground. NOW,
I was wondering about the end of that inverted "V".....it goes right into and near that 80m loop ! I believe that the inside the 80m loop is where the "action" is. It doesn't matter if the
loop is delta,or square,or even totally round! IS MY inverted "V" leg of the dipole interacting
with the loop ?? I have plans to RAISE my 80m loop up another 15ft. higher....will I get problems when I do ?? One leg of my 160m antenna goes right in the middle of my 80m loop. IF the LOOP goes higher will it intereact? So far,at how I got things set now....no major issues. I never use both antennas at the same time.

Great Place
to "air" antenna ideas......HERE.

Thanks, RayN kb1-ghh

Thanks, Jim, with Richard C's help I finally downloaded all of Reg's great works from his web site.

Reg's daughter, Jean, has posted her approval of our keeping her Dad's memory alive by continuing to use his web-page material.

Hello Jean (which happens to also be my wife's name),

I'm glad that you're pleased with our keeping your Dad's website alive--it would be a sacrilege if we didn't.

I should tell you that when traveling to England three years ago, also while on the North Sea traveling back to England, I sent several emails to your Dad, which he failed to answer. After returning to the US I pointedly asked him if he received my emails why didn't he respond. I was disappointed to learn that he didn't feel comfortable at receiving guests (I wanted to visit him), because he was sensitive about his appearance. I understood that, and forgave him for not answering. However, I would have very much liked to have met him, but I still have his portrait downloaded from his web site, from which I'll see him from time to time, never forgetting him.

Again, I'd like for both you and your brother Peter to accept my sincere condolences on the loss of your wonderful father, Reg.

Walter Maxwell, W2DU

Hi Ed,

As the download process finished the count showed 3.0 MB. However, when I later entered his web page address separately, I found some additiional information that failed to come up in the download that took up 22,8 KB. This additional material contains detailed information about Reg the person, including his portrait, showing him to be a jolly, friendly and handsome English gentleman. Make sure you access this material.

Walt

Well done, sir.

What I know about Reg is he was one of those rare people with an extrordinary innate instinct for physical phenomena. I knew one other person with that level of understanding of things natural, and he won the Nobel Prize for Physics in 1995.

For me it was always a little bit of a strange feeling when Reg would contribute to a discussion on this newsgroup in which I was participating, knowing that among other things, he was a part of the

greatest technological achievement of its time. An accomplishment which by any measure is still monumental. And that was when he was just getting started. We should all hope to leave such a wealth of achievement.

73, Jim AC6XG

Thank you very much, Walt. That isn't large at all, in this day
and age of huge audio and video files, so I will make sure I get the
info, including the extra you mentioned.

It sure pains me to hear of the passing of classic and exceptional hams like Reg. It is a sign of the aging ham population, I guess.

Jean and Pete,

I always enjoyed your dad's comments, although as some others, I
didn't always agree with him. I think some who disagreed overlooked
his subtle humor and took his remarks much too seriously. I sometimes
suggested, always in jest, that maybe he had sampled too much of that
evening's bottle.

Regardless of the technical disagreements it was impossible to not be
disarmed by that photo of his wonderful countenance on his web site.
It was nice to have known him even from afar and via this medium. We
will miss him.

So as I hoist a glass of good California red I too say, "Cheers Reg!"

Warmest regards,

Wes Stewart, N7WS

There's another way to put your 80m loop on 160m for
NVIS operation. Cut the 80m loop directly across from
the feedpoint and install a good insulator. Use that
configuration for 160m and short out the insulator for
all higher bands. I'll let you come up with a cute
shorting arrangement because whatever switch you use
has to withstand thousands of volts on 160m.

A 15 watt PEP SSB transmitter on 11 meters will do just fine for your application.

If the propagation is open, 15 watts will work the world.

If propagation is NOT OPEN, 25,000 watts will works to just over the horizon [well maybe a little back scatter.] Two Hundred and fifty watts is just wasted money.

In the olden days, when 11 meters was an Amateur Band, I worked every state in the eastern USA with 7 to 8 watts and an indoor antenna.

Hey, "Dave," since when does the FCC mandate all hams MUST
"work DX?" [try to remember that "the DX community" does NOT
issue/grant/authorize amateur radio licenses, only the FCC]

"Working DX on HF with CW" is an OPTION, not a requirement.

In fact, the FCC doesn't even mandate 'working' a foreign
radio amateur at all. ['foreign' meaning any country outside
USA jurisdiction]

>It's your choice: if you want to play the DX game learn the rules including 25
>wpm CW.

"Dave," you really need to be reminded that the FCC does NOT
mandate/require/encourage ANY "DX contacts." Neither does the
"DX community" grant any licenses OR make any "rules" that ALL
US radio amateurs must follow.

Oh, and "Dave," the REAL US amateur radio regulations require
passing a FIVE WORD PER MINUTE (equivalent) manual telegraphy
test (15 words per minute with the "farnesworth" approved
equivalent rate), not "twenty-five words per minute."

"Dave," have you been licensed a long time? I don't recall ANY FCC requlations requiring a "twenty-five" rating, only the OLD regulation (prior to mid-2000) and that only for Extra class. I'd say you really ought to review the latest rules that apply in this new millennium. You can review those for free at the United States Government Printing Office website under "Code of Federal Regulations." You can also get it at the ARRL website since the ARRL seems to think they are the only "official" source for everything amateur...

>If you want to operate an appliance, but an appliance.

You mean EVERYONE "following the rules of the DX Community" uses homebuilt radios? All have built their own keys so that they don't use appliance keys? Amazing...

How does anyone "but an appliance?" :-)

Beep, beep,

["Dave" is a suspect banker in the investment trade?]

>The time investment is not as much as it seems.

Dee, the "time investment" for MORSEMANSHIP depends entirely
on the psycho-acoustical aptitudes of the learner. "Learning"
a psycho-acoustic skill is NOT an intellectual one, it is a
physical one.

>That is even more true of
>someone who has experience in related fields or has experience in the art of
>studying. For those with some existing experience in related fields, they
>can often read up enough in a single weekend to pass the Technician written.

You morsepersons need to get a common story. The rabid morsemen
keep saying it is all "memorization," taking no skill whatsoever.

>This will let you get your feet wet in the VHF/UHF and higher frequencies.
>There's quite a lot that can be done in this area if you invest in the
>equipment.

Come right out and say it...you morsepersons consider the
frequency world above 30 MHz to be beneath you, a place for
kids and lids (and probably space cadets) to go and PLAY.

>Again if you have some related background, the General written is not
>particularly time consuming to study for either.

Everyone can just "memorize" the answers, right? :-)

>The code is only as hard
>as you make it by fighting yourself. If you decide that you will learn it,
>the average person only needs about 30 hours to get to 5wpm, assuming that a
>good training method is used.

The ARRL VEC uses the "farnesworth" method which send at FIFTEEN
words per minute...even though the FCC regulations have five.

Dee, you haven't addressed the subject of the existance of the
manual morse code test itself. You (erroneously) think that it
is "necessary," possibly because you had to take that test.

>Getting the General license gives you all modes and all bands and the
>maximum power privileges. The only thing you do not get are some
>subsections on some of the bands that are reserved for Extra licensees.
>
>Now the Extra test is quite a bit more difficult but is not required unless
>you want to get into those subsections mentioned above.

Extra class are the "elite." Having an extra license allows all
the preening and self-righteous attitudes possible in a hobby
activity. It is personally rewarding to elitist-wannabes who
have to be "better than ordinary persons."

>You spoke of "learning as you go". Basically ham radio is the same. Even
>the Extra class license has only scratched the surface of all that might be
>involved in amateur radio.

Really? All those extras in here seem to think they are FAR
better than any professionals in radio...because they had to
test for morsemanship.

>The tests & licensing are to insure that you
>know enough not to get hurt, not to cause harm to other people, and not to
>make a mess on the bands. Also they are to insure that you have a grounding
>in the basics so you don't go spinning your wheels trying to get things
>working.

Golleee! All along I thought the FCC just regulated (and
mitigated interference) in ALL US civil radio. Their
predecessor agencies (before 1934) used Licensing and Testing
for same as a REGULATORY tool. I didn't know that those were
also academic tests and diplomas...

>You might ask why this is important.

Why IS morsemanship so important?

> Let's just address the safety area for a moment.

FCC amateur radio regulations cover only the radiated
RF power field. As a safety issue for ALL affected by
that RF field. Does YOUR station obey the federal
regulations?

>Well for example, you can actually get a burn from grabbing an
>antenna that is being used to transmit.

Why would anyone do that? [anything in official rules on that?]

>If you get into microwave
>transmissions, you could fry your eyes (or somebody else's) if you look into
>the end of a wave guide while it's being used to transmit.

Why would anyone do that? You can get far worse damage to the
eyes looking into a laser beam of much less power...and you
don't need any license for that.

>You can get
>electrical shocks from feedback due to a poorly set up station. This is
>just a small sample of some of the things that you should be familiar with.

Those aren't covered in FCC regulations, are they?

"Feedback gives one shocks?" I suppose...I've made feedback
networks for years and never been "electrically shocked" by
them. Delighted and surprised that they worked so well,
perhaps, but never got any electrical shocks from feedback.
I guess I'm just not "amateur" enough...hi hi :-)

>suppressed carrier. [SSB = Single Side Band]

"Dave," your knowledge of Single Sideband is ferklempt.

The spectra of an amplitude modulated signal was mathematically
described by John R. Carson of AT&T before the 1920s. SSB,
including suppressed carrier, was USED by the telephone
infrastructure in the 1920s for long-distance lines. The most
common system, "C Carrier," had four separate 3 KHz voice
channels and would operate on the open-wire telephone lines
then common all over the world. This "C Carrier" was directly
adapted to HF radio in the early 1930s, the frequency-multiplexed
total signal converted to HF and amplified. The first HF SSB
radio link was put into service between the Netherlands and the
Netherlands Antilles carrying four voice channels or (to become
the later commercial-military standard of two voice and six to
eight TTY channels). While single-channel SSB was experimented
with before WW2, it didn't expand until after WW2 and a number
of US military contracts awarded to then-prominent radio makers
(Collins, RCA as two examples). Based on that success, the
amateurs took it up in the 1950s while the ARRL promoted the
false idea that "SSB was pioneered by radio amateurs."

Technically, your statement was faulty. Each "sideband" (the
spectra adjacent to the carrier) carries ONE QUARTER of the
total RF power output of single-channel SSB, not "half" in
normal AM. In normal AM the carrier is always constant in

amplitude. In normal AM receivers the "detector" stage is a mixer, combining the carrier with the two sideband spectra with the output lowpass filtered to yield the original audio signal. Single-channel SSB usually suppresses the carrier (almost to extinction) and the "detector" stage being fed an equivalent constant-amplitude carrier signal from an internal receiver oscillator. The mix products of carrier re-insertion and the input single sideband spectra yield the original audio modulation after lowpass filtering.

The important thing about single-channel SSB is that a transmitter peak power output of RF need only be one-half to on-quarter of a conventional AM transmitter to yield the same demodulated audio signal level.

No morsemanship skill is necessary to use a single-channel SSB radio. Today it is being used on the open sea by both commercial and private boat/ship owners for voice communications; also data, separate or multiplexed, for written communications.

The duties of the Tennessee STATE Guard (not affiliated with
the National Guard) were described by them as a sort of
in-Tennessee 'custodian' of NG facilities if and only if the
NG there is activated into federal service plus being a sort-of
'military police' for that state. As quasi-MPs they would have
some ability to access federal records to confirm Robeson's
military service. On the other hand, the TN STATE Guard will
(by their own statements) accept membership by civilians.

The morsemen have been so brainwashed into believing their own
efficacy in radio that it is impossible to "win" anything,
certainly not with the ARRL publishing house constantly implying
that morsemanship is the "best" skill an amateur could have.
Amateur morsemen are so wrapped up in their personal skill that
they are unable to come to terms with any amateur or
professional radio person who doesn't care for it. To them,
US amateur radio is ALL ABOUT manual radiotelegraphy. Tsk.

>You can't just plug a radio into a computer and start using them.
>Digital communications doesn't work if you do it that way.

No? You mean you can't buy a rig from HRO, unbox it, and
connect it, and have it work right away? :-)

There's several transceivers on the market that DO that,
Big Al. Have you kept up with radio technology since
Spark was outlawed?

>>Can you give me valid reasons as to what useful purpose in today's age they serve?
>
>No, since someone who wants instant gratification can't be bothered to
>listen to why that's the wrong way to do something. Your time is
>probably much to valuable to spend it learning enough to understand
>why you can't learn enough in an instant.
>
>Go memorize some test answers, get a code-free tech, hook your
>computer up to your radio and, in 6 months, you'll have your radio up
>for sale on eBay, because "it doesn't really work".

Is eBay where you sold your radios, Big Al? :-)

Hey, Big Al, have you written the QPC yet about those simple,
easy-to-memorize questions on writtens? No? Why not?

Have you written the FCC yet about the anyone-can-get-a-ham-
license and tell 'em "what for?" [it's easy to submit a
petition to get back to them good ol days you want, FCC tells
you the procedure on their website] No? Why not?

Maybe you ought to write your congressperson, then. Tell THEM
that US amateur radio testing has gone down (your imaginative)
toilet and DEMAND that something be DOME about it!

You sure are ANGRY about things, Big Al. Maybe you need some
tranquilizers or mental therapy? No, you say? Okay, then I'll
just put you down in the Cranky Old Coot category. Here, have
a Foxtrot Uniform with my best wishes... :-)

Hello,

I'm not sure whether I have a good picture of your situation but there are some general rules.

In general, magnetic field lines generated by the loop that are parallel with the wire from the inverted V, do not induce voltage into the wire. On the other hand when the E-field lines are perpendicular to the V's wire, there will be no induced voltage in the wire.

Imagine a plane that cuts your loop (inclusive the tuning capacitor) into half. The loop is perpendicular to the plane. Every wire that passes along or inside the loop and stays in that symmetry plane obeys the above statement, and interaction will be negligible. The above is valid when you loop is fed fully balanced (no common mode current on feed line).

When you use the V, the loop will introduce some capacitance to the V. It is best to keep the wire away from the high voltage ends (where the tuning capacitor may be present), because a slight deviation from the symmetry plane will cause interaction between the loop and the wire.

Besides this general rule, also wires running close or through the loop, but off the symmetry plane may be acceptable, but prediction is difficult. You are able to measure the effect. When you make a kind of common mode (current) transformer with a diode detector (with a suitable ferrite the you can place around the feed line), you are able to detect the common mode current (when transmitting).

If you run the questionable wire of your V through or along the loop and the output of your transformer does increase significantly, there is (undesirable) interaction.

I hope this will help you.

Best Regards,

Wim

Hello Bob,

Your suggestion will very likely increase the reception at MW and lower HF. It will probably not increase reception at VHF and UHF.

I am not familiar with your receiver, but when you connect a long wire directly to the input, the receiver may be overloaded (check with the attenuator). Also transient phenomena (for example lighting) may damage the input circuitry.

I use an OAR 8200 "DC to light" receiver, but in Europe (Netherlands) it is unusable with a wire (strong overload), I made a tunable filter. The disadvantage of the filter is that when I change band, I have to retune the filter. For VHF I use a flat plate dipole optimized for 110 to 170 MHz (made of wire mesh). For wide band coverage from VHF to UHF, you could use a discone antenna. Also here you may experience overload problems when you are close the a transmitter.

A complete other option is to use a wide band active antenna, Maybe you can find a design that runs from long wave to VHF based on a FET. Here you also may experience overload problems

I hope this will help you

Radio Shack has a discone that receives from 25 mhz to 1300 mhz. Maybe
you could combine that with a random wire for the lower frequencies.
(The arrl antenna handbook has a discone for 7-30 mhz, but it is 62
feet tall -- you could check their formula for what it would take for
500khz to 440 mhz)

Here is my spur of the moment opinion... think of the frequency you want to monitor and thing of the antenna. Then realize that to get a reasonable signal you need an antenna that is substantially large in terms of the wavelength of the signals you want to capture.

If you want to monitor HF, MF, and even lower frequencies, a standard VHF discone such as the diamond D-J130 is such a tiny fraction of the wavelength of HF signals that there is very little HF signal captured by it.

You need wire, and plenty of it, if you want low frequencies!

> ...but morsemen aren't happy. :-(

It's not the Gay 90's anymore. But maybe before the 1st decade of the
new millenium lets out, we'll have a decision from the FCC.

> >> >Robesin is a national hero, taking part in seven hostile actions as a

The sad thing is, even if he were to finally tell the truth no one
would believe him.

> If Robeson comes clean and ever shows any documentation now,
> he is in for tons of remarks of his past claims that he can
> never weasel out of, not even with the gratuitous personal
> insults he normally uses against challengers.

And so, robesin can never come clean. He will go to his grave with
lies heaped up, pushing up the daisies.

> If Robeson continues on his fraudulent claims, then he is
> only repeating his present behavior, convincing no one, and
> building only his own warped fantasy. The rest of us will be
> stuck with his personal blog output.

We know better. We are stuck with nothing, the nothing that is
robesin.

I pity anyone under that flight path. They don't know the danger they
might be in.

And the CAP and American Taxpayers are liable.

The technical aspects of antennas are complex, and some of the readers of this group (such as myself) are unable to fully participate in discussing the fine points. I want you to know that your dad was one of the handful of highly respected antenna gurus who discussed these technical issues. I learned very much by reading his posts and thinking about his views. The newsgroup will not be the same without him.

Wayne

I was jesting on the "JAG" part. :-) Robeson-Robesin has been on
such a jag trying to impress folks (as a fraud) that his posts have
enough material for at least two seasons of "JAG - a personal
story."

mike

3444. Flexible Coax for HT instead of remote Mic

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-01 02:36:13 UTC
From: "Bob D." <bobmgtd@insightbb.com>

Source record: 53431

I'd like to use my HT in the car. I figure why should I buy the remote microphone when the HT itself is the size of a microphone. All I need is coax that is flexible enough to withstand the rigors of a mic cable. Anyone know of a source of flexible coax?

(I have a few feet of Columbia Super-Flex RG-58, but it's 35 years old and really beat up. Do they still make it?)

Thank you, Rick! You spoke volumes of reality in this new
millennium.

"Slow Code" is a relic of the 1930s, mentally over 70 years in the
past.

Some portables get so hot on 12V (13.6V) that you can't hold them
after a short period of transmission. One of the benefits of a 5W
matchbox sized radio!

Why try to design and build one if you can get a 900 to 2600MHz version
for US$12 or a 2 to 11GHz version for US$6. See Ebay items 300021857426
and 300021856873. How about 400 to 900MHz for US$24, item 300021857046.
Cheers!
Bob

Now did I open a Pandora's Box or what LOL.

Ok let me put this out there. Instead of me using CB's how about Mobile
Ham. I know I have to get a ham Lic. The one I would go for I think is
called a Techn. Lic. This way all I have to do is take a writen test
and yes I pass on the morse code.
Thoughts?

http://www.antenex.com has them - part number CPL9CF is a crimp-on
female PL-259 for RG-58 cable. Antenex dealers such as Falcon Direct
carry the same part, same number.

I am looking for a female version of the standard PL-259 connector. It connects the same way a 259 does, but is simply a female version.
I called The Wireman and was told they no longer handle these connectors due to no interest.
My goal is to make a jumper cable (I've seen these connectors at Rad Shack on pre-made cables) with a male on one end, a female on the other so as to add a 25 ft. length of cable without having to mess with a barrel connector.
Anybody know where this can be found? And, NO, I am not in the market for an SO-239.

Jean and family,

You have great reason to be proud of Reg, both as a person, and as an exceptional ham! He had incredible physical intuition, and was one of the few people who knew how a piece of aluminum in an electromagnetic field "feels." He was kind and patient enough to share that with those of us who don't those skills.

My thoughts and prayers are with you and your family in this time of loss.

A female PL-259 will have the threaded ring on it- how will you deal with 2
threaded rings being mated together? What you ARE looking for is an in-line
SO-239. Pasternack and The RF Connection both carry them for cables from
RG-58 to RG-213 sized cables.

Hello,

I am a littlebit in doubt to buy an AT1500DT diff-T tuner of Palstar and
sell the AT1500CV T-tuner.
At the moment i use a Palstar AT1500CV for my vertical with a great joy and
maybe the AT1500DT will work better ?
Can someone say the cons and pro's about the AT1500DT ?

Here's a brainteaser for you, Jim. Assume the following example
under steady-state conditions:

XMTR--X--tuner--Y--one second long lossless feedline---291.42 ohms
Ps=100W Pfor=200W--> <--100W=Pref PL=100W

The lossless tuner is tuned for a Z0-match so there is zero
reflected power at point 'X'. The Z0 of the feedline is 50
ohms. The voltage reflection coefficient at the load is
0.707 making the power reflection coefficient 0.5

We suddenly disconnect the source at point 'Y'. After the
source is disconnected, how many joules of energy are delivered
to the load? _____

How many seconds does it take to dissipate all the energy in
the feedline? _____

On a second by second basis, how much power is delivered to the
load after the disconnect? _____ _____ _____ _____ _____

3459. PC Board Capacitors at HF

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-01 14:30:21 UTC
From: "n3ox.dan@gmail.com" <n3ox.dan@gmail.com>
Message-ID: <1157121021.156335.44310@p79g2000cwp.googlegroups.com>
Source record: 53446

I want to make a couple of L networks to match a 20m delta loop to 50 ohm coax on 20m and 17m; 100W max. I know I can use a transformer on 20m, but I figure I'll save my ferrites if I'm building L networks anyway, and to be economical of junkbox parts, I'd also like to save my air variables.

Would capacitors made of PC board be decent transmitting caps at these frequencies, provided they didn't break down? The board is hamfest surplus special... so I don't know what it is, but it may be G10... it's a dark green fiberglass material, about 2mm thick dielectric. Comparing the capacitance of a 2 inch square of the material (88pF) to a parallel plate cap with air dielectric of the same physical dimensions (12pF) gives a dielectric constant of about 7.3.

I'm going to try it anyway, but I'd appreciate any input anyone has about the suitability of unknown PC board as HF transmitting capacitor material, primarily with respect to dielectric losses.

If it matters, the 20m network is a 1.14uH series inductor with an 88pF capacitor shunting the antenna side. The 17m network is a 3.08uH series inductor with a 29pF shunt. The 20m antenna impedance is about 250+j0 and the 17m impedance is about 950+j1200. I figure there might be some voltage breakdown issues, but worst case, I smooth the edges of 2 or 3 2x27pF or 3x27pF caps and put them in series.

Thanks and 73,
Dan

I'd consider _that_ a plus. Helps rein in the motor-mouths.

What the OP needs to be concerned about is not so much the flexibility of the feed line, but, rather, the sturdiness of the coax connector at the HT. That 'joint' will take a lot of stress in such a mode of operation. Not only will there be problems at the point where the coax enters the male connector, but the large stresses on the female connector will oft times ruin the internal attachment to the pc board.

Back before the banality of VHF FM operations drove me away, I would make up a little plastic 'back-board' that attached securely to the HT and extended up a ways to help support the coax. As well, I slipped some over-sized tubing over the coax to move the flexing away from the coax connector.

3461. Re: How far can you stretch a discone for receive only?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-01 15:10:46 UTC
From: Bob Bob <bob3bob3@cox.net>
Message-ID: <n4vls3-kor.ln1@p400bob.personal.cox.net>
Source record: 53448

Hi Bob

There isnt a simple answer to your question! You havent really defined what "usable" really means either.

As a gut feel however a discone would probably be "usable" over a 10:1 frequency range (say 44-440MHz) There will be some tradeoffs however, the most troublesome (in my view) being non optimal radiation pattern as you go higher in frequency. (ie the antenna pattern tends to sky) It will never work as well as an antenna designed for a specific frequency. Your only real option is to try it and see.

Below about (say) 20MHz you'll probably get better performance just using the feedline to the discone. You might even consider separately RF earthing the R3 and then only connecting the centre conductor of the discone coax. You will of course encounter local noise issues but it does work.

Its a hard call to find an antenna to do what you want unless a lot of compromises are accepted. If I was in that situation I'd probably grab one of those motorized car radio antennas type designs so I could adjust the length remotely, or look into some kind of (remote adjust) magloop design for at least the HF end.

Apologies for not being much help

Cheers Bob W5/VK2YQA

3463. Re: PC Board Capacitors at HF

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-01 17:31:59 UTC
From: K7ITM <k7itm@msn.com>
Message-ID: <1157131919.578091.78620@i42g2000cwa.googlegroups.com>
Source record: 53450

For the 20M case, the RMS voltage at 100 watts is only about 160. Especially if you trim the copper back a bit from the board edge, it shouldn't be a problem. The 17M case is about 500VRMS at 100 watts. Even that probably won't be a problem. (I have an SO8 IC in front of me that claims to be OK with 600 volts between adjacent pins: less than half the thickness of your board.) Since the board area is so small for that 29pf, why not just try it? The thing I'd be most worried about is corona at the sharp edges of the board. If you were to make the capacitor plates circular, that would help. In addition, if you soldered a ring of, say, 12AWG bare copper wire to the edge of the circular plate on each side, that would make a rounded edge. If one side of the capacitor is "ground" anyway, just leave that side's copper the size of the board, and trim back only the other side. The outer edge of the PC board copper circle would just touch the "donut" of copper wire. A cap like that would probably be good for several thousand volts, assuming the dielectric extended out several mm past the circle. Fiberglass-epoxy isn't the best dielectric for a capacitor in terms of high frequency loss, but should be OK for your low power. But is it really standard fiberglass-epoxy? If it's standard 1.6mm thick, I'd expect no more than about 70pF with 4 square inches of plate area. A relative dielectric constant of 7.3 is too big for standard FR-4/G-10 material. You may need to put some RF current through it to test to make sure it doesn't heat up too much.

I really don't think you'll need to put caps in series to get what you want. In any event, instead of making three separate capacitors, you could just add an air gap between two pieces of your copper-clad material...or use some dielectric other than air if it's easier. But some nylon screws and nuts (the nuts acting to space the boards), or even steel ones out on the periphery away from the capacitor plates, should work fine. You could even make it adjustable that way, by adjusting the spacing...

Cheers,
Tom

If you aren't going to solve the problem I posed, then I don't see why I should feel obliged to bother with any more of yours. Only seems fair. There is a significant point to my question that you still have not addressed. Would you have us believe that some new revelation is being presented by this latest problem of yours? Or perhaps it's simply intended to divert attention away, once again, from my question.

Or maybe it was just too hard for you. How about a simpler problem then:

XMTR--X--one second long lossless feedline---infinite ohms
PS=100W

How many Joules are stored in the transmission line? Why?

I've also found that HTs are less than ideal for mobile ops for
another reason - squelch. Most of them do not have a separate squelch
knob - you have to go through a menu to change the squelch setting.
Not a good thing to do while driving - it's the sort of thing which
makes J. Random Cellphone User's distracted behavior seem downright
civilized.

Add to this the fairly wide-open nature of most HT's RF front ends,
(and the resulting sensitivity to intermod), and the amount of 2-meter
RF noise and birdies from cable leakage, etc., and you end up with a
bad mixture.

An HT with a magmount antenna will do in a pinch, but I don't feel
that it's a good long-term frequent-user solution in an urban area.

My 5 watt IC-T7H will transmit a signal that is 100% copyable by satellites 200+ miles away. We have been trying to tell you; "The issue is NOT POWER!!!"

You are focused on power. You should be focused on the range [miles or km] you wish to cover reliably. Tell us how you intend to use your radio then we can give you a more meaningful answer.

But, the SO-239 is the natural 'mate' for the PL-259 :-)

Build your cable with PL-259s on both ends. Then buy a UHF Adapter Jack-Jack,
Amphenol P/N 83-1J.

<http://www.amphenolrf.com/products/CatalogPages/unf_catalog.pdf>

This is the easiest way to achieve what you want to do. The 83-1J is available
at HRO et al distributors.

/s/ DD, W1MCE

Hello Dan,

About your matching network for loop antennas:

Breakdown will not occur through the material in your case. Major issue
is dielectric losses.

As you know the antenna impedances, you are able to calculate the
apparent power for the capacitor (just Ic*Uc [rms values]). Both
Epsilon and loss factor for FR4 varies (depending on the manufacturer).
You can use 0.01 as a rule off thumb. So if your capacitor "consumes"
an apparent power of 500W (at 100W input), the loss inside the
capacitor is about 500*0.01 = 5W.

I hope this will help you.

So far, Robeson has NOT been convincing. He IMPLIES and ALLUDES
to things but hardly ever states anything outright and then
never with any referencible sources that anyone can access.

Robeson has tried to construct an edifice, indeed almost a
temple in which we should all venerate his mighty
accomplishments AND, at the same time, has leveled barrages
of personal insults and deragatory accusations against all
challengers. That latter action negated his mighty
constructs and established his fraud. That 'edifice' has
to be torn down...if for no other reason than being an
eyesore to us in his field of dreams.

In reality, the STATE Guards (not all states have them) are
little more than state political constructs to enable a few
to play soldier and otherwise establish their machismo. Part
of that is the ever-present "conspiracy theory" coupled with
some kind of imaginative armageddon scenario of a doomed
future where everything in a state is in ruins or anarchy but
the "state guard" can step in and "restore order."

The curious thing about the latter is that some of the Believers
in the efficacy of morsemanship think in the same manner...that
only amateur radio survives the worst emergency and that only
morsemanship can be used to call for help. That is patently
absurd in light of reality but founded on the mythos of morse
that grew following the Titanic disaster of 94 years ago.

As to fully-activated National Guard units, the states have
various plans to keep the NG structures and land intact,
usually using civilian personnel (law enforcement, probably)
and that does not require a lot of personnel. In the field
of communications for the REAL public safety agencies, those
agencies are well-supplied with many forms of communication
of their own (outnumbering amateur licensees according to EIA
data of about 15 years ago) that is NOT part of the "telephone
infrastructure" that many ham-patriots erroneously think
"always fails in an emergency." Most public safety agencies
in the USA have established emergency-scenario plans and
they periodically train/drill for those procedures. Very few
amateur radio local organizations do that.

For several months past I simply did not bother accessing Google
for this newsgroup. It was a waste of time when the macho
middle-school mental-adolescents came in and talked trash and
filth to anyone. How many of those anony-mousies were actual
amateur radio licensees is unknown and irrelevant. The known
licensed amateurs just didn't do anything about them. That
presents a very BIG negative on the amateurs' ability "to
police their own." They couldn't. They can't despite their
brags about such "policing."

Robeson once made claims that he was IN one of the local Los Angeles HRO stores, with "friends while visiting them." A big problem with that was that was his claimed time-line and NOT being able to describe, even in minor detail, the locations or the surrounding territory. The first HRO in northern L.A. was in Van Nuys, CA, in the center of the San Fernando Valley. [bought my Icom R70 there years ago] That HRO moved to Burbank, CA, a few years ago, at the corner of Buena Vista and Victory (a major intersection with shops at all four corners). It is across the street from a relatively new food supermarket having a huge elevated sign visible from all four corners. Robeson could not describe that sign, let alone the location, even though it was easily visible (he didn't name the supermarket). It is very familiar to me since my wife and I shop there regularly. Robeson couldn't name a single store in the mini-mall across the street from the market even though there's a Radio Shack outlet next to that HRO. That HRO has now moved again (they had a window sign announcing that for weeks) and we will see if Robeson wants to repeat all of his lies about being in any one of them. :-)

>
>> Guess the wannabe DILL sergeant told me, huh? :-)
>
>well real boot camp would pleasenter than what Robesin would devise
>
>I know Boot camp was accuauly the most fun I had in the army

Brian and I were being sarcastic about "boot camp." The US Army and the USAF *never* had "boot camp." In those branches is was called BASIC TRAINING. It still is and is usually referred to familiarly as just "Basic."

I "took Basic" at Camp Gordon (now Fort Gordon) which was in 1952 a Signal Corps center and now THE Center for Army Signal Corps. We had to learn basic infantryman soldiering, how to "close with the enemy and destroy them." No fun in that part of Georgia near Agusta. The only communications taught in Basic were courier duties and connecting/using an EE-8 Field Telephone plus laying field wire (real grunt work carrying that auto-pay-out wire box on a back pack). After 8 weeks of Basic we were assigned to Signal Schools...Field Radio and TTY at Gordon, radar-microwave-photography at Ft. Monmouth, NJ. For me, "fun" didn't begin until Monmouth and the ability to actually handle radios, examine their guts and theory, use them on the air.

Things have changed greatly in military communications since 54 years ago. The Field Radio MOS long since became extinct and with it the need to learn manual radio-telegraphy. HF radio is still taught but more as an adjunct to VHF radios common from small units to battalion level...the SINCGARS family of digital voice/data, optional frequency-hopping and encrypted modes with a quarter million produced since 1989 and all operational...to be replaced soon with a compatible but upgraded family of radios with more and better features. HT-sized SINCGARS-compatible radios are being used in Iraq and Afghanistan now (you can see them on news telecasts). The ONLY radiotelegraphy classes are centered at the Military Intelligence School at Ft. Huachuca and that for (passive, listening-only) Intercept Analysis purposes, not communications.

Some non-active or never-serving morsemen in here have insisted that Special Forces "use" radiotelegraphy since a Special Forces Communications Sergeant MOS is required to know that. Special Forces are very macho in image but they, like the USN SEALs, are a very small group of specialists, for (as their name implies) Special operations. The major Army and land-force marines effort is done by regular land soldiers. "Behind the lines" (quaint euphemism) comms can be done by regular land signal units by encrypted data over VHF-UHF, relay by aircraft or satellite, extemely hard to intercept. Even in the 1990 First Gulf War there was no "CW" used from "Behind enemy lines." The AN/PSC-3 did that or, in a few locations inside Iraq, by VHF voice or data.

The extreme mobility of USA land forces now, and in 1990, is described in the many land-forces reports done on the First Gulf War, namely Operation "73-Easting." The final hundred hours of the First Gulf War outdid the best panzerfaust actions of Rommel in North Africa of 1942-1943. About two orders of magnitude better. One thing that the American military did copy from Rommel's units was "Nevis" or NVIS, Near Vertical Incidence Skywave, short-distance ionospheric bounce that some hams deride as "cloud burning." Nevis works rather well and has been a field procedure in USA-USMC-USAF land-to-land comms for at least a quarter century.

World War 2 was over 61 years ago. Vietnam War was over 33 years go. The First Gulf War started (and finished almost as quickly) 16 years ago. The Korean War went into a state of perpetual Truce 53 years ago. Amateur morsemen still gorge their imaginations on the Titanic disaster CW comms of 94 years ago. Time has gone on and technology has changed...for all but those hidebound morsemen are still pipe-dreaming their

imagined glory and self-steam after watching old WW2
movies on late-night TV, demanding that future amateurs
learn morse to defend their homeland. :-)

Jim Kelley wrote:
> Or maybe it was just too hard for you.

It was impossible for anyone to solve without having
a math model for the sources.

> How about a simpler problem then:

This is not simpler - it is contradictory. It provides a
constant power source with nowhere for the source power
to go during steady-state. If you change the source to
a Thevenin equivalent then it can be solved.

> XMTR--X--one second long lossless feedline---infinite ohms
> PS=100W

Please explain how the XMTR can supply 100W during steady-
state? Where does the 100 joules/sec go? As stated, this
problem, like your other one, is impossible to resolve.

If you change the source to a Thevenin equivalent 141.42V
and 50 ohm source impedance and specify Z=50 ohms feedline
impedance then the problem becomes solvable. The answer is
that 200 joules exist in the feedline and, contrary to what
W7EL states, will dissipate in the source resistance after
the source voltage goes to zero. Note the source resistance
is the only resistance in the entire circuit.

A day or so ago I was searching the Internet, looking for a discone antenna. Today, after a routine virus scan of my system, I see that ZoneAlarm quaranteened a Win32.Softomate trojan horse, which it described as a dangerous "back door" type that lodged in my registry. It was able to delete it, but evidently the thing was able to get through both the ZoneAlarm and Microsoft firewalls undetected.

I mention this here because, in trying to retrace my steps to deduce where the trojan horse probably came from, I remember one person's site visited looking for a discone antenna. It was different in that I was led to a page where I clicked on a link that turned out to be a page of dumb girly pics. I exited right away, but it seems possible something got downloaded.

So keep your antenna up.

Antenna Theory:

There are many textbooks telling that an antenna
to be effcient needs "much wire in the air".
Now the time has come to correct this view.

This new view is based on many practical tests
on all HF bands over a year.
As en example read the email below.

The antenna used for this contact was 3 meters
long and 1.5 m above ground. (= RoomCap Antenna)
The contact was on the 160m band over a
distance of 600 Km.

With Jim's lackadaisical approach to conservation of
energy, there is no "correct" answer. He didn't even
tell you what the forward and reflected power readings
were. He also doesn't seem to realize that a 100W XMTR
cannot force any power into an infinite load. I am trying
to apply some boundary conditions that will remedy that
problem.

So Richard, what do you think happens when a constant
power output XMTR is facing an infinite load? What
happens when an irresistible force meets an immovable
object?

Why in a text-only forum?

I also notice that you use Microsoft Outlook Express and that this
"Trojan horse" is specific to Internet Explorer as an advertising
toolbar.

Given that you are publishing MIME format to this group, and that your
browser picked up an infection, you should review the security
settings AND publishing preferences for both M$ tools.

Another solution is to switch to securer platforms like Firefox for
browsing and another newsgroup (and email) reader (I use Agent which
is absolutely untied from DLLs).

Stop using IE and Outlook. Msft only provides protection for a price.

Set your news reader options to read and post only text, no HTML.
Set your emailer the same, text only.

Turn off javascript in your web browser's preferences/options.
If you really need it on, then make sure it's worth the risk
and turn it back off when you're done.

Turn off all non-essential system services when connected
to the net. The only ports you should show listening on
windows are 135 and 1025 (AFAIK they can't be turned off)
and they should be set to be blocked by your firewall.

Good luck and safe surfing.

a lackadaisical 14 word apology replacing a 3 word admission of not
knowing - and across two postings. No doubt this will be followed by:
1. more lackadaisical postings;
2. more lackadaisical words;
3. no answer.

It's curious that you haven't denied that 100 Joules is NOT the right
answer! At least Jim went that far, if no further. In a two man race
you have managed to put yourself in third place.

In this country, there is regulation that requires availability of a Material Safety Data Sheet (which contains such information), and they are on a public web site. Perhaps you have similar arrangements in your jurisdiction.

I just located an MSDS for Ox-Gard via a web search, and it's quite
unrevealing. It doesn't identify the ingredients except to say that
they're non-toxic, and it doesn't identify a flash point. It did say
that combustion could release CO2 and aldehydes.

Hi Owen,

That information has been considered a secret that is vital to the interests of the United States of the Republican Party and is on the list of items not allowed on board airplanes, nor to be transported by skateboard across the border of any state contiguously bordering Texas, except Venezuela. Those Data Sheets have been removed from the public archive by the CIA so as to eliminate any possibility of this newly classified material falling into the hands of terrorists.

Don't ask us about toothpaste or the FBI's network monitoring will kick into mauve alert level.

You might have gotten some priviledges, but that was only because ham
radio has been dumbed down and you didn't have to make an effort to earn
them.

You're too friggen lazy to put forth an effort to earn anymore
priviledges, that's why you want ham radio dumbed down.

Now, if I lived near you, I would do CW practice for you to upgrade. I
honestly would. What you should do if you have an HF receiver is to try
to find some code on air to practice copying.

Maybe you could talk N9OGL into making Omega One a code practice station.
He could send Code practice runs in between all the shitty songs he plays.

Oh well, it was worth a try.

What I didn't add, was that you may need to be a chemist to work out
what the components are, or to use Dave's hints and work out what is
in it that produces those combustion products.

I was just chatting with a friend who lugged his 2m gear up on a
mountain top here in the national capital to work some AE DX.

A newspaper reporter noticed him and came back with camera to do a
story. I don't know if the public will understand that although he is
using directional apparatus to bound electromagnetic radiation off
passenger aircraft, that it is truly safe for all involved.

Wait a minute, no one has been able to prove radio frequency EM
radiation to be safe, have they?

Owen

I may be a relative simpleton here, but the transmitter won't know that for 2 seconds, Cecil. I bet some power may manage to get into the transmission line.

The best course is to go stand next to an old lady,
preferably one who looks wealthy. Let fly with your
pressure-release, then turn to the old lady and whisper
loudly, "Look innocent, lady, and everybody will think
that *I* did it!" :-)

Of course, I said that it was possible from a Thevenin
equivalent circuit. But Jim said the XMTR was putting
out 100 watts into an infinite load during steady-
state, obviously an impossible mental boundary condition.

A Thevenin equivalent circuit will supply 100 joules/sec
into the feedline and then stop supplying power. That
is not an impossible mental boundary condition. I'm
ready to discuss that configuration.

My cousin is a Dairy Farmer in PA.
His cows produce more CO2 per hour
than three GMC Pickup trucks running
at idle for the same time period. Wonder how
Mr Goore would address this problem?
Diapers for cows perhaps? (grin)

Back on topic however, when you get back to the office
next week, just place a call to the mfgr of the product and
ask him to FAX or e-mail you a .pdf file copy of the
Product MSDS sheet. Tell them you're using it at your place
of employment for anti-corrosion usages for commercial
antenna installations and your ISO:9000-2000 Internal
Quality Procedures Manual mandates that all products have
an MSDS sheet on file. I use this 'method' all the time and
it seems to work. :)

I've got an additional bit of advice.

Be very cautious about what you delete after being told by a program that it's malware. The programs I use have targeted quite a number of innocent files as allegedly being malware. Not too long ago, I had to spend considerable time writing code to replace a purchased third-party utility package which had been part of EZNEC for years. Some of the spyware/adware programs had decided, completely incorrectly, that it was some evil spyware. I finally got tired of customers asking why EZNEC wouldn't run, then having to explain that it was because they'd deleted a file that it uses and needs.

Browse through the testimonials for the various malware-detection programs and you'll see "Wow! Found 14 files none of the other ones found!" Yeah, and those are some of the same ones you'll see comments like this for: "I began using XXX, and now I can't connect with the Internet." or ". . . and now my computer won't boot." Or, ". . . and now EZNEC won't run." There's a lot of poor software out there. Don't blindly believe everything it tells you.

Soak a bit up with a piece of paper or cardboard and light it with a match, and you'll have the answer in seconds. Petroleum based grease will burn like crazy but silicone based grease won't.

But why do you need to know?

Felix, dude, repeat after me:

"We believe in the one way, the addition of fields, radiated from wires, combined spatially in phase to give gain, or loss, or fire in the case of too much loss. We believe in the fundemental difficulty of delivering power efficiently to physically small radiating structures, and we understand the limitations it places on such structures as compared to their full-size counterparts. We believe in the QSO, and that any antenna can provide many enjoyable ones. We believe in your puny 160m signal, that we dug from the noise with our phased Beverages, and replied in kind with our legal limit and transmitting four-square, and you received us well, yea and verily, despite your use of a dummy-load. We believe in the gain, 20dB or more, that an antenna may exhibit when it or its plans are meant to be sold. We believe in the measurement, scientific and clear, showing clear quantitative comparisons to a suitable reference aerial; let it now be done, or may you fall silent."

73,
Dan

I found my Outlook Express had correct settings, but not using them, plus
the blocked senders list was no longer working after I erased stuff there.

So now, as suggested, I am off IE and OE and have gone to Firefox and
Opera. Maybe I'll check out the new IE 7 when it gets out, though.

Thanks for the heads up.

Further Info: Pasternak's Catalog #2006C page 134 shows what you want.
Depending on whether you are using RG58 or RG8, and depending on whether
you want crimp connector (requires special crimp tool) or clamp type, they
have it all.

www.Pasternack.com or 866-727-8376

Ed K7AAT

Thank you Dave, Dale, and Ed for taking the time to not only respond, but to
show me where to find this connector. May you make many DX contacts in the
coming months.

Hello Felix,

Regarding antennas that are very small with respect to wavelength.

With regards to your example, no correction to antenna theory is necessary. Small antennas can be efficient radiators, but the smaller the antenna, the more difficult to achieve reasonable efficiency.

Antenna theory is well established. When you know the current distribution in a structure, one can calculate (mathematically or numerically) how much power is radiated (and also how much power is dissipated in the structure). This approach is used by virtually all Antenna Design software packages.

All electrically small antennas have one thing in common, the usable bandwidth is small. The Q-factor of a lossless electrically small structure is proportional to
about 0.05*lambda^3/Volume.

For example a small loop of thin material with infinite conductivity has higher Q-factor than a loop of same diameter, but made of very wide strip (with infinite conductivity). The last one occupies more volume and therefore has lower natural Q. The Q-factor of practically small antennas can be that high that the bandwidth may by just a few kHz.

The problem is in the matching. Matching, for example 0.8 Ohms in series with a reactance of 2800 Ohm (Q=3500), to 50 ohms is not easy. The Q-factor of the components is not high enough, some or most power is dissipated in the additional components, or even the antenna wire itself. So in the end your antenna may have an overall efficiency of 5% (-13 dB). Also voltages can be that high that power is lost by corona effects. Often, due to the high local E- and H-fields, power is lost in nearby constructions.

About the practical use of small antennas. In many cases received signal levels are in the S9+20 dB range. As the noise level is far below this, loosing 13 dB (so your signal level will be S9+7 dB), is acceptable. If not, you may increase the input power. In the end, the small inefficient antenna is at least better then no antenna.

So in my believe, a nice QSO over 600 km with a small antenna, doesn't prove that antenna theory has to be revised.

I'm very curious to see the construction details.

Best regards,

Wim
PA3DJS.

As the problem was stated, I have NO reason to include 100
joules in the set of correct answers. I also have NO reason
to exclude 100 joules from the set of correct answers.

If Jim had specified that the forward power and reflected
power in the one-second long lossless stub was 50 watts
each during steady-state, then we could conclude that
there is 100 joules in the feedline.

What textbooks say that? EZNEC says that a 3 meter tall monopole has a maximum gain of 1.5 dBi on 160m while a 38 meter 1/4WL monopole has a maximum gain of 1.36 dBi. In other words, they radiate approximately equally well both with high radiation efficiencies.

The problem is not with the antenna's ability to radiate. The problem is in getting the RF energy into the antenna.

The problem is not with losses in the antenna. The problem is finding an efficient j2250 inductor for the matching network.

If we knew what your matching network looks like, we could estimate its efficiency.

Cecil Moore wrote:
> If you change the source to a Thevenin equivalent 141.42V
> and 50 ohm source impedance and specify Z=50 ohms feedline
> impedance then the problem becomes solvable.

Going with this configuration which is similar to the 1/2
WL stub suggested by W7EL in his Food For Thought #1:

SW
Source nc c Pfor=100W--> <--Pref=100W
141.4V---o<---o---one second long lossless 50 ohm stub--open
50 ohm
o---/\/\/\/\/\--Gnd
no 50 ohms

For the first two seconds after power up, the Thevenin
source delivers 200 joules into the stub while dissipating
200 joules as heat in the source resistance. Those 200
joules of energy in the stub must be conserved.

During steady-state, assuming the stub is an exact integral
number of wavelengths, the source will see an open circuit
and be delivering zero power. A wattmeter calibrated for
50 ohms will read 100 watts forward power and 100 watts
reflected power during steady-state.

After steady-state is reached, we throw the switch and connect
the stub to a 50 ohm dummy load. 100 watts will be supplied
to the dummy load for two seconds for a total of 200 joules.

Who was it who said that reflected power cannot be
recovered? (Food For Thought #1 on www.eznec.com).

Methane, Dave.

I won't say that global warming is happening or not. However, the science is sound regarding CO2, methane, and other gases that tend to retain heat in the atmosphere. The relationship between these levels and heat retention is fact.

Perhaps there are mitigating factors going on. Perhaps ocean life can sequester the excess CO2, perhaps something else?

Instead of picking on "Mr Goore", perhaps you folks that know better can provide scientific evidence of the mechanisms that are countering the so called "greenhouse effects.

Radiation resistance, and the r-f resistance in the path for induced ground currents back into a practical antenna system have a larger effect, though. Here are some numbers for two vertical monopoles of about the same scale of height to width.

If in both cases the matching network has a 2 ohm loss, there is a 10 ohm loss in the r-f ground connection, and both antenna systems present a 1:1 match to the tx, then with equal tx power output the peak power actually radiated by a 1/4-wave monopole will be about 65X (18 dB) greater than by a 3-meter monopole on 160 meters.

I'm speaking of CO2 based global warming, whether as the results of say volcanic activity, or as a result of the amount of CO2 added to the atmosphere as a result of combustion release.

May I assume that you believe that glacial cycles are the sole source of global warming or cooling?

Hi John,

Cecil's answer, like those of so many politicians, embraces a faulty
premise to dismiss discussion. Imagine those same administration
savants on the upcoming 5th anniversary asking for yet another board
of enquiry for a study into the possibility of WMD in Iraq. That
didn't happen, and yet we get this interminable "Global Warming isn't
so, and it isn't from ____" (fill in the blank with any of a number of
their favorite red herrings).

What's the difference between WMD and Global Warming? What caused the
rush to Iraq, but not to the melting glaciers? Wrap a side of bacon

around Global Warming and it would be covered with Republicans like flies on their favorite nourishment. ...perhaps if the Eskimos had gotten to Jack Abramoff first instead of the casino Indians....

Hmmm, a thought occurred, and a little research reveals some interesting metrics. Oil at Nymex Crude Future is at $69.19/barrel and Evian (Mineral water from the Alps) is running for $1.69/pint. Simple conversion reveals Evian outdistances Oil at $743.60/barrel. Obviously I was wrong about the bacon, Global Warming has Chateï¿½ubriand wrapped around it. I'm surprised the Pentagon hasn't got F-35's backed up to the glaciers with their after-burners going 24/7/365. Oil-for-water! And a conversion rate that beats taking graft for a living.

Next week, how Creation Science will have our cars running on water to wean us from terrorist oil.

Not the sole source - just the primary source.
120,000 years ago, temperatures peaked higher
than they are presently. These cycles occur in
100k-120k year intervals. CO2 levels always
zoom up and trail off gradually during the peak
temperatures. There is some sort of feedback
mechanism that takes the CO2 levels down.

Mark, you have to give up on this anonymous "Slow Code." He is just another of the Bigot Morsemen. He cannot adjust to changing times, changing technology, or (perhaps) changing his underwear.

The FCC establishes regulations for ALL United States civil radio. What the FCC says, goes. The ARRL doesn't rule, morsemen don't rule, and old, old traditions don't rule. The FCC has NEVER said anything about "earning" a license...a license applicant must take an FCC-approved test and score above an FCC-established minimum percentage correct answers. That's all there is. FCC regulations are LAW and that LAW can be changed by democratic principled means. That LAW is not established by some minority group who cannot advance beyond primitive on-off carrier keying.

This "Slow Code" (like all bigoted morsemen) has taken up a role of "I-am-your-leader" gang-banger bullshit bragging and usual calling names of those licensees "below" him. Poor guy (or gal?). That's all this "Slow Code" has...SOME manual morse code skill. He might be right at home in an 1870s telegraph office but his attitude is neither for democratic principles, nor for good fellowship in a hobby, nor as a human being participating in a discussion forum.

The FCC doesn't "rule" on any amateur radio "traditions." It simply regulates ALL US civil radio (amateur radio is a small part of that) and mitigates interference when it happens. The FCC follows the LAW in their charter, permitting an open forum for Comments on NPRMs, even R&Os, open for ALL citizens and even allowing Comments from non-citizens.

Bigot morsemen do NOT allow any opinions opposing their own over-inflated self-defined opinions. They want to RULE all the Homies in da Ham Hood. They think they "own" ham radio when the only thing they've "earned" is a bad attitude against them. It's a wonder they haven't taken up Spark transmitters (even though damped-wave mode is forbidden by law). Spark and morsemanship went together in olden days, days well before the existance of any of the bigot morsemen in this forum. "Slow Code" needs a time machine to go back to that old era since he can't keep up with modern times nor the democratic principles of the representative republic of the United States of America.

As a professional in radio communications, one who began in and on HF over a half century ago, I have contempt for the over-inflated egos of the bigot morsemen. None have made their case valid enough to warrant morse code testing for amateur radio licenses forever. But, the ARRL is toadying to them, vainly hoping to increase their minority membership by sticking to the amateur practice of a half century ago. ARRL membership hasn't increased beyond a quarter of all licensed radio amateurs in the United States, nor has the ARRL favored, ever, the VHF-and-up amateur radio licensees beyond the barest minimum of mentions.

Sooner or later the FCC will yield to PUBLIC pressure to modernize US amateur radio beyond the old-fashioned limitations and favoritism towards morsemanship lobbied for by the ARRL. It may not come in "Slow Code's" lifetime since he is of the group where a morse key has to be pried from his cold, dead fingers. Poor "Slow Code," old before his time, unable to fit into this new millennium of radio technology.

Hi All,

I saw Albert Brooks movie "Looking for Comedy in the Muslim World"
last night that had a routine by him that reminds me of this
boot-shuffling, toe-scrubbing side-step:

Brooks (to an audience of mixed Muslims, Hindus, Sikhs....):
"We are going to investigate the humor of improvisation and I need you
to give me a nationality"

"German!"

"OK, German. Now how about a occupation?"

"Farmer!"

"OK, a German Farmer. What does he raise?"

"Turnips!"

"Is he married?"

"Yes, with 5 children!"

"OK, is he rich or poor?"

"POOR!"

"OK, a poor German Farmer, married with 5 kids who raises Turnips.
That's great, we are going to have a lot of fun with this. (starting
to rummage up a routine, and then changing his mind) No, I don't like
him being German. We are going to make him Chinese, but Chinese don't
raise beets, they raise rice and they are doing pretty good, so he's
not poor.

"So, we have a middle class Chinese rice farmer with 5 kids - NO! I
read somewhere they have a population limit, and I don't want him
married. Let's make him divorced with 1 kid.

"No - raising rice is such a stereotype, so let's make him a bus
driver.

"OK, a divorced middle class Chinese bus driver with - No, I hear Japan is really getting into this divorce thing. OK, a divorced middle class Japanese auto worker with no children! Imagine him asking for a raise:
"I want more money! Chinese make more money raising rice than I do! Even Germans eating turnips do. Give me money!"

Yeah - right.....

Yes, tailored to a configuration that is possible
(Thevenin source) rather than the previous impossible
one (100 watts into an infinite impedance).

So far, Jim has refused to discuss all possible
configurations and seems to prefer only the impossible
ones. One wonders why.

Did you initiate a tune? Unlike some other tuners, the EDX-2 will not initiate the tune automatically, you need to initiate it and presumably you have interfaced the EDX-2 to the Icom's tuner interface.

If you have done all that, the relays rattled, and you have 3:1 VSWR, then it sounds like the EDX-2 is faulty.

Owen

I have not seen such a thing, I doubt it.

>
>I don't have an AH-3 to look at, but does it also have a daughter
>board? Schematic??
>

IIRC:

I have used an EDX-2 on an IC706IIG.

The protocol is very similar, the EDX-2 is the dumber device, so it ought be just a matter of pinout adjustment.

The EDX-2 does not accept "abort" commands, and it doesn't send a "fail" response, so the integration is not quite 100%. But it will respond to the Icom's START signal, and assert the KEY line until it has tuned... which will work OK with the Icom.

Beware that the different Icom models use this interface in different ways, and the IC7000 continues that tradition. It seems that it is very important that the connection to the tx KEY line is open collector, otherwise the tuner interferes with proper fan operation.

Thanks for the information!

Yes, I have to push the Tune button on the 706 and the relays rattle
and then the red LED light on the 706 lights up. The built in SWR
meter shows a 3:1 SWR. I can change the frequency on the 706 and get a
lower SWR.

I have noticed that the tuner does not "Tune" for very long. No where
as long as the DX70 took and it seems like maybe the "tune" process is
being cut short. When I change bands, it takes just a half a second to
tune which seems way too fast.

Is this information give any more clues to what is going on?

The EDX-2 works fine with the DX70. (I can change back & forth using
adapter cables)

Thanks,

Don>>>

Ok, so when you change freq after completing a tune, how low does the VSWR go and how far away did you tune at what freq? You probably need an external meter to get better resolution in making this measurement?

It may be that the two detectors in the EDX-2 are out of cal, and it is finding the wrong tune point.

>

No, not necessarily a problem. The EDX-2 like many, store a cache of recent tune positions, and it measures f, searches the cache, tries the settings and uses them if ok, otherwise it retunes.

Do the same test on exactly the same frequencies as I suggested at the start of my reply. The results should be exactly the same.

One meter gives two possible answers: right or wrong
Two meters gives four possible answers:; right/right, right/wrong, wrong/right, wrong/wrong.

Three meters gives eight possible answers: .... etc.

How much difference are you seeing?

Are you sure you have no common mode rf on the coax?

IS the IC736 putting out sufficient power to properly activate the internal meter?

etc.

Go for it, Congenial Fred, show 'em who's boss in da ham hood!
:-)

Ya know, US amateur radio is supposed to be about good
fellowship and all that warm and fuzzy stuff. Poor Fred
long since ran out of warmth and his mind is fuzzy...tsk.

What are YOU "better at," Congenial Fred? Morse code? I'm
sure you are a whiz at that. Anything else except getting a
bad score on the range after shooting off your mouth? I'll
bet not.

Wow (yawn) 50 years a ham (and still not cured). I've been
a professional in radio longer than that. Fascinating stuff
that radio and electronics technology. Morse code isn't
technology per se...it was being done over 40 years before
the first radio-as-a-communications-medium was demonstrated
in 1896. But you "are better" than non-morsemen because you
passed a NON-TECHNICAL, NON-INTELLECTUAL manual morse code
test...as an AMATEUR. [big Ben Stein "wowwww" here]

"Welfare license?" Just because there's no manual morse
code test for Technician class? Oh, my, but the FCC does
NOT say anything about "welfare licenses." That's only your
own BIGOTRY vomited up. Almost half of all US amateur radio

licenses are now in the Technician Class. Are you deliberately trying to alienate half of all ham licensees? Well, Congenial Fred, you are doing real good on that alienation part.

Have fun on "the bands," Fred, there's plenty of your kind there, the bigoted morsemen, the self-proclaimed gods of AMATEUR radio trying to be "leaders" in da ham 'hood.

Fred, support stem cell research. You've lost too many neurons required for good fellowship...maybe some stem cells can help restore them.

Brian, sudden realization! We may have found the illegitimate
biological father of Stebie Robeson!

Same ego, same "better than you" bad attitude, same lack of good
fellowship, same 9-year-old's sass, same-o same-o! Incredible!

Then again he may be a cousin to that anony-mousie "Slow Code."
Lots of inbreeding going on in the morsemen ranks.

I wonder where Jimmy Noserve is hiding? Fred said "shut up!"
Jimmy would have a hissy fit if'n he saw that...:-)

I extend fellowship to REAL hams, you no code idiots are not hams, simply CBers that have the ability to read at a third grade level.

Everyone serves a purpose, even if only as a bad example... No code, non showering, non intellectial, whiners holding welfare licenses meet that criteria to a "T".

Now that you have been responded to in the manner you accuse all code able hams of, you may cease your trolling...

I don't really give a flip one way or another if you ever know code, I just wish the bunch of you would stop playing "pity me" and lamenting the fact you do not have a no code Jesse Jackson type to take up your cause. You have a license, enjoy it and if you don't care to learn the code, someday you won't have to. In the mean time shut up with the whining and get on with life.

The license is only worth the investment you have in it, no effort - no value! If you spent half the time learning as you do bitching you would be at 40 WPM.

> last four global warming cycles?

What are you talking about Cecil? You are presupposing that the "other" side is saying that all global warming is due to Human activity.

It isn't. Volcanoes can belch out a lot of the stuff. There is a good chance that methane ice at the bottom of some parts of the ocean can "let loose" a lot of global warming material.

Of course the obvious answer to your question is "not humans".

And equally of course, the question is not relevant.

There are many answers to your question. No doubt that precession has a lot to do with it. The Sun itself can vary. I can't imagine that the Deccan Trap episode of volcanism didn't warm things up after the initial cooling effect it must have had. Didn't have a thing to do with human beings.

But your argument has a fatal flaw. That not all causes of global warming are caused by humans does not mean that none are.

Not quite. Haven't you seen the warnings to both CBers AND hams about "freebanding". And what CBers do are not Riley's purvey outSIDE the ham bands. That comes from the Dallas Field Engineering Office and is headed up by Mr Brock.

And in RH's defense, if you want to do something positive, the next time you are out cruising in your HF mobile, dial up 28.085 AM and just listen along the interstate. When you hear a trucker yapping on his "export reddio thar, drivah", just copy down his company name on the door, DOT number (to verify the company), tractor number (usually on the door or side of the hood), date/time and frequency and location and send it to rholling@fcc.gov. He will then issue a warning letter requesting the company to contact him to "discuss' the matter! The companies don't like to get letters like this, and will act to stop their drivers' illegal radio activity. It *was* quiet along Interstate 85 for a short while, but now the drivers are back yapping as usual. They are all over the country doing this and it is up to licensed hams to do, at least, SOMETHING to stop it!
So how do you observe them doing this? One way is that they see hams' screwdriver antennas or multiple antennas and they remark on "their secret, spay-shul truckers' channel (thar)" like....."He shore has a lot of 'antanners on that car", or "Git a load of that big 'antanner'; betcha he kin tawk to China". (Little does he know it CAN!). A small tape recorder works well! ;) It looks like a mike, so the trucker likely won't even know what you are doing!

So let's get out there and record these stupes and get them lettered! It *may* not stop it all, but anything is better than nothing at all (like whining and complaining about what someone ELSE isn't doing :))! And, yes, I am told that there SEVERAL companies we *should* be hearing about soon! At

least I HOPE so! If it is allowed to continue, can we expect to find them on
15 Meters with Super-Duper Cobra "ham" reddios wid 2,000 "channels" (thar?)

Please stop confusing inclusive assertions with exclusive
assertions.

That is NOT my argument. My argument is that it has not
been proved beyond a reasonable doubt that man has any
primary effect on global warming. "Man-causing-global-
warming" is a religion, based on faith, IMHO. In fact,
it seems more likely that man's CO2 contribution to the
atmosphere will do nothing more than hasten the next
ice age.

Take a look at the slope of the C02 buildup of 120k
years ago just before the last ice age. It is very close
to the slope of the C02 buildup of today. There is evidence
that ~280 ppmv levels of C02 triggered ice ages 120k, 240k,
340k, and 440k years ago. That's about the level of CO2
today. There is reason to believe that another ice age
is poised to happen and the Man-causing-global-warming
religion will no doubt blame man for it.

Some thoughts upon reading the article...

I wonder which "arm of the Milky Way" we "passed through", and what area of "intensive star creation" we passed through. Celestial mechanics and time-scales being what they are, the answer would (should) be obvious.

BTW, we are IN an arm of the Milky way, there are no other nearby galaxies, save Andromeda, which although rushing toward us, is still comfortably far away. Perhaps the Magellanic clouds?

I notice on page 56 of the article - page 6 of the he pulls out the political trump card.

Quote from article:

"The Mann et al. papers had a political edge: They served as a counterweight against President George W. Bushï¿½s negative stand toward the Kyoto Protocol as ï¿½fatally flawed,ï¿½ and his attempt to lessen the economic global catastrophe that Kyoto would induce".

WELL! At least this fine fellow wasn't being political!!!

Sorry Cecil, as a political piece, this has some merit. As science, it treads dangerously close to creationism.

And in the end, it fails to explain what I want all along. That is:

The effect of Differing amounts of CO2 on atmospheric thermal retention has been a well documented fact since the 1840's. Assuming that there is no effect on the global temperatures from combustion that releases more CO2 into the atmosphere than would normally happen, what is the mechanism that compensates for this release?

I've heard a few things, such as increased planktonic or increased
vegetation sequestering, but shouldn't that keep a pretty
tight, ie close control over the situation?

Great place to start: use your meter to measure
SWR normally, and then REVERSE it! Antenna to rig
connector, Rig to Antenna output connector, and
then calabrate it BACKWARDS (full scale in the
SWR position, and then MEASURE your SWR , in the
Calibrate position! If you dont get the SAME
reading of SWR, then the sampleing lines arn't
ballenced! This shows up most often, at VHF!
Give it a try- meter should read the same BOTH
WAYS! If not try adjusting the sample loop
toward, or away from the coax section, until they
read the SAME on SWR ! Diodes and the diode
sensitivity DO make a DIFFERENCE!
as info, Jim NN7K

Right. In your opinion.

> ice age.

Yeah, Cecil. I read the political-crypto-scientific article in your link. It wasn't science. It had a political premise, then tried to build a scientific story around it. Seriously, if the solar system passed through an arm of the Milky way with extensive star formation, which one was it? Did an arm of the Milky way come unattached and attack our particular arm? Celestial mechanics isn't easy to open to political attack, at least since the Pope pardoned Galileo.

What I am trying to say is "where's the beef?"

Sigh... Why do I get the feeling that you are giving me some ready made arguments for someone else's questions? I'm not arguing whether or not man is causing global warming, or even if there is such a thing. I want to know why an increased amount of CO2 in the atmosphere is not warming the earth, when it should be (experimentally speaking)

No Republican, Democrat, or religion answers accepted. Just science.

Yes, and the 11 year sunspot cycle has been a well documented
fact for thousands of years. Does puny man have any more
control over the 100K year CO2 cycle than he does over the
11 year sunspot cycle. Methinks you (and others) suffer
from delusions of grandeur. Why do you think the CO2 levels
ALWAYS drop after they reach ~280 ppmv? Do you think man
can do anything to block that ~100k year drop in CO2 levels?

Something causes an ice age every time the CO2 level
gets up to a threshold of ~280 PPMV, approximately
what it is today.

You have time scales a tad messed up. WE don't have any control over the log period cycles.

Methinks you (and others) suffer
> from delusions of grandeur. Why do you think the CO2 levels
> *ALWAYS* drop after they reach ~280 ppmv? Do you think man
> can do anything to block that ~100k year drop in CO2 levels?

Cecil, you are making arguments as if I am some kind of dyed in the wool tree huggin hippie back to the cave days left wingin' democratic commie leebural.

And yet you haven't provided one single non-political (and not scientifically flawed) oriented debunking of the CO2 effect upon the atmosphere.

No delusions Cecil. I await enlightenment. You argue in the same vein as creationists. If you wanna have an intelligent argument, fine. If not, fine.

Tell me why the CO2 levels *ALWAYS* drop after reaching 280 ppmv. I await. Otherwise, I'll allow you to have the last word, and continue on your way. Science isn't a debate, despite what creationists, Anne Coulter, and creationists think. It is how things are.

chasm,

There is a fundamental flaw in your approach. You cannot have confidence that the meter you buy for $100 is significantly better than the two you already have, and so, it doesn't add useful information in solving the problem reliably, it just adds complexity and noise.

Some key tests that you can perform on the MFJ969 are:
- does it indicate 1:1 on a good 50 ohm dummy load (and that the internal load doesn't qualify as a good 50 ohm dummy load)? (Goodness is 1:1);
- terminate the MFJ with a S/C and measure the forward and reflected power, are they exactly the same at any power level(reduce your transmitter power output to do this test)? (Goodness is that they match exactly at all power levels);
- terminate the MFJ with an O/C and measure the forward and reflected power, are they exactly the same at any power level(reduce your transmitter power output to do this test)? (Goodness is that they match exactly at all power levels);

If it passes all those tests, it may be ok. We have not validated the scale shape, nor the absolute power calibration (which is not needed for VSWR measurement). You cannot do either of these easily without a reliable means of measuring RF power, voltage or current.

What's that, you don't have a dummy load! Oh well, go ahead and use the internal load... but remember it is not as accurate as you would want, and so contributes to error. (I shouldn't be surprised however if the MFJ969 meter is calibrated (ie nulled) on the internal load so that customers think that since they agree, they must be correct... remember what MFJ stands for! Seriously though, if you tightened all the loose screws, shook out the loose solder bits, clipped ends of wire, extra nuts etc, the sampler and meter in the MFJ969 are good enough for the purpose at hand.)

Indicative readings from my MFJ949 (which uses the same sampler / metering), on the internal load with 100W fwd, reflected is ~0.5W (very hard to read, using the low power scale, non linear) which is a VSWR of 1.15. On an external Bird load I cannot see meter deflection (this might not be the factory cal, I may have cal'd it along with other repairs.)

Owen

Fred HaFrom: Fred Hambrecht on Sat, Sep 2 2006 6:02 pm

>I extend fellowship to REAL hams, you no code idiots are not hams, simply
>CBers that have the ability to read at a third grade level.

Tsk, tsk, Fred. Had you been able to read RRAP before, you'd
know I have no amateur license, only a commercial one. :-)

So, you think that US amateur radio is defined ONLY by
morsemanship? Of course you do. You are unable to cope
with any other definition. The FCC doesn't think so,
Congenial Fred. Only you and the rabid olde-tyme
morsemen think so.

>Everyone serves a purpose, even if only as a bad example...

You fill that bill to a "T" Congenial Fred. :-)

>No code, non
>showering, non intellectial, whiners holding welfare licenses meet that
>criteria to a "T".

"Non showering?" :-) Shirley, you can think of some
metaphor better than that! :-)

"Non intellectial?" Oh, you mean 'non intellectual."
Tsk, tsk, Congenial Fred, if you wish to appear 'intellectual'
you really ought to learn to spell correctly... :-)

"Whiners?" Poor congenial Fred, can't understand that there
are several valid reasons being held by the majority AGAINST
morse code testing. You want to impose YOUR imperial will
on the majority... Tsk, tsk, not a nice democratic
principle idea.

"Welfare licenses?" I got my First 'Phone in 1956, one test
session at the Chicago Field Office of the FCC. Had to pay
my own way in on the train. No snow, ground was level, and
I kept my shoes on the whole time. Guess that isn't near as
good as all them olde-tymers in the ham boonies, huh? :-)

>Now that you have been responded to in the manner you accuse all code able
>hams of, you may cease your trolling...

Fred, you've shown yourself to be a first class morse BIGOT,
one with a totally closed mind who lives in the past. But,
that's not unusual among some of you kids (your birth year is

1939 but mine is earlier). After you hit the magic 65-year
mark you go all shirty and start whining yourself about how
"tough" YOU had it and how "loyal and principled" you are
and how the "younger generation is no damn good" because they
don't like YOUR ideals of a long-ago youth. I know, I've seen
it hundreds of times...and am damn glad I never succumbed to
such mental sickness. :-)

Oh, and I do NOT "accuse all code able hams" of anything, only
YOU, Fred Hambrecht, and all the other morsemen bigots who
trash-mouth everyone who doesn't care for morsemanship.

I don't "troll," congenial Fred, I CATCH. I've presented my
views before the FCC clearly, logically, with facts researched
and noted. Many times. I don't sing praises about morse code
or testing for the simple reason that there's no praise for
either.

>I don't really give a flip one way or another if you ever know code, I just
>wish the bunch of you would stop playing "pity me" and lamenting the fact
>you do not have a no code Jesse Jackson type to take up your cause.

Tsk, are you a racial bigot ALSO? I'm not black, congenial
Fred, don't fake any religious titles nor academic titles nor
the usual bragging bullshit common to so many amateurs. I've
been on this planet longer than you have and made my own way
without asking for welfare. Up yours and enjoy your food stamps.

Well, maybe no "Jesse Jackson" but you pro-code-test mavens DO
have the Church of St. Hiram on your side plus all the Brother
Believers in Newington alla time singing the praises of
"cee-double-yew" that all good maxim-fearers must follow.
To the letter. To a "T."

>You have
>a license, enjoy it and if you don't care to learn the code, someday you
>won't have to.

I have a license, Freddie baby, but it NEVER had any requirement
to learn morsemanship skills. I've had other FCC licenses,
Freddie, and those didn't have any need to learn code. Of course
those were all commercial-professional, not the mighty amateur
kind (which you no doubt consider much, much more valuable).

Freddie booby, 53 1/2 years ago the US Army had me and
several others starting to operate HF transmitters of higher
output power than was ever allowed to amateurs. NO license
test needed. NO morsemanship skills needed...NO morse code
modes were used to keep dozens of circuits open 24/7.

I didn't have to know or learn morsemanship over a half century
ago and haven't needed it in all the time up to now. You come
along like some adolescent male and talk trash to me and other

no-code-test advocates and say I "must?" Oh, my, you must
think your morsemanship skills are super-macho with
superpowers!

>In the mean time shut up with the whining and get on with
>life.

Shut your own, bigot Freddie. You get NO breaks acting
like a morseman bigot. Bigots don't deserve any civility.

"My life" is going on just dandy without you, Freddie. Try
to stay out of it. Intrude on it and you get stepped on.

>The license is only worth the investment you have in it, no effort - no
>value!

Oh, wow, trotting out the "moral paragon" ploy are you? :-)

Sounds like you are getting ready to enter the seminary at
the blessed Church of St. Hiram!

>If you spent half the time learning as you do bitching you would be
>at 40 WPM.

One "learns" a psycho-motor skill? :-) It is DEVELOPED,
Freddie boy, isn't one damn thing "intellectual" about it.

Pressing the government for a change in certain laws, such
as the regulations concerning amateur radio licensing, isn't
"bitching," colonial Fred. It is simply a democratic
process to change archaic laws and regulations that have no
use today. But, you fear change. Such might detract from
your mighty self-image of an amateur morseman, god of radio,
and ruler of the ham-ways. :-)

Or is it that you want to CONTROL others, have them do as
YOU command and to hell with democratic principles of law?
Clarify that for us, Freddie, you seem to be swinging both
ways.

Freddie, there is zero-point-zero interest in "learning"
any psycho's motor skill in this new millennium. It isn't
used for communications in any other radio service under
USA regulations and won't be...except in the time-retarded
imaginations of some US radio amateurs who dream of ever-
lasting glory of the beeperman.

There is one helluvalot MORE INTERESTING, INTELLECTUAL
things to do in learning the theory behind the front
panel. Don't speak blithering drivel about "beauty and
majesty" of monotonic on-off tones while caressing your
vibroplex...the only "theory" there is turning something
on and turning something off. You can do that with a
buzzer if it turns you on so strong.

You want to do 40 words per minute using morse? Fine. Go for it. I've been doing ONE HUNDRED TIMES that with data and that's at a slow speed. The world's comms aren't about manual telegraphy, Freddie, that's a long-past time that began before you and I were born. It is OLD stuff.

Now you go right ahead and enjoy your "ARS" (Archaic Radiotelegraphy Society). I'm sure you feel all authoritative with your federal AMATEUR license and all. Tell everyone you are "federally authorized." Invite your friend and neighbors in to view your mighty license certificates (suitable for framing). Feel proud for you are a MORSEMAN! [god of radio, ruler of the ham-ways, etc., etc., etc.]

Beep, beep

3587. Convert DISH TV antenna for WIFI use. USB or RF FEED?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-03 05:26:41 UTC
From: Kaz <rowdy1970.UCE@hotmail.com>
Message-ID: <lltKg.930$l71.63@trnddc01>
Source record: 53324

I am looking for an easy way to convert a standard DISH TV offset feed dish for WIFI use. I desire to mount this thing on the rooftop for a long distance rural link. I need to understand if it would be easier to go the USB device route or what the ramifications are to going the traditional rf and coax route? I think my install will require around 60 to 75 ft of feed line. Could I use a wifi "extender" amplifier at midpoint to get past feedline losses? If I go the coax route, what would be an easy way to feed the dish? Could I use a tiny off-the-shelf external wifi antenna inside of a can or do I need to homebrew something more extravagant?

If I go the usb device route to feed the dish, how can I extend that far?

I do need to connect this to a pc as a NIC or client, therefore remote mounting a router wont do the job for me.

You need to check the regulations for an unlicensed device in the U.S.
There are EIRP (radiated power) restrictions and using a dish antenna
may exceed them.

Since this is a ham radio group, I assume you have a ham license. This may
complicate things, because WiFi is not legal for ham useage. WiFi is very
specific in what is legal or not, so are hams, but they are different.

For example, the modulation method may not be allowed, encryption is not
allowed, commercial useage etc.

> I do need to connect this to a pc as a NIC or client, therefore remote
> mounting a router wont do the job for me.

Without some sort of device to manage the protocol, WiFi is pretty usesless.

Geoff.

> RON....KA2IIA

Not really. The differences would be so small a receiving station wouldn't note any difference. The exception being if the radials are buried deeply (more than 3-4 inches).

What is important is the number and length of the radials. For more information check out http://k6mhe.com/BLE.html

Source record: 53232

Hi Kaz

My first thought is to go the USB route, 60-70 ft of coax on any WiFi band is a substantial loss that has to be (RF path) budgeted for. If you are trying to save $ by using the "ex" dish, the coax and connector costs can really blow the savings.

Have you actually modelled the link you are wanting to setup? There are a number of GPL s/w packages that will help you out here. You'll then know what your margins are in determining what mode to use.

Note that I dont know how effective the extender amplifiers are. Have a look at their specs and incorporate them into the model too.

I dont know the max distance for USB but I guess an extender cable would do it. I asume that is also a freq/distance/loss thing like the old RS232 standard was. The simple answer is to lower the cable data rate till it works.

I am sure you can also get WiFi repeaters if that is an option. I know Cisco WAPs have that option as well.

Sorry, my knowledge isnt so complete on this subject.

Cheers Bob VK2YQA

Okay, I understand now. You don't actually know, perhaps don't even care to know, but you do know you don't like any of the proffered explanations.

Just as a point of info, the "weak sun" solar constant during Precambrian times is at odds with the temperatures that they were seeing at the time - keeping in mind that "time" is a vague reference to the warm periods.

Paleosol data indicates that CO2 concentrations were much lower than would be needed to offset the solar constant, and that CH4 levels of 100 - 10000 ppmv would have been needed to compensate.

Sooo, CO2 levels by themselves are not a good indicator of "the whole story". CH4 is an even stronger greenhouse gas. It's also produced by life forms. Humans, termites, ruminants.

There is something to look into. Perhaps the regulating mechanism is based on that? Maybe the next leeburull plot will be to take down the bean industry by banning them! ;^)

> I also don't
> know why the nucleus of an atom contains quarks.

Quarks are just smaller "points" of matter that make up protons and neutrons. Nothing mysterious there. I think part of the confusion is over the goofy names that physicists insist on giving them.

3600. More Long Wire Questions

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-03 14:51:21 UTC
From: "Bob D." <bobmgtd@insightbb.com>
Message-ID: <IKGdna7D6pRGdmfZnZ2dnUVZ_o2dnZ2d@insightbb.com>
Source record: 53237

What impedance would an end-feed infinitely long wire in free space have? I'm about to put up 60 ft of wire 30 ft above the ground, and pipe it into my living room. At first I intended it for 'DC to Light' receive only with my new IC-R3 toy. But now I'm wondering if I could transmit into it on 2M and 440. (I know this sounds chincy, but it's bound to get out better than a rubber duck.) I figure at VHF and UHF 60 ft of wire would look like a beverage antenna, except this wire is going to be many, many wavelengths above the ground. So what does a wire many, many wavelengths long, many, many wavelengths high look like? Would I need a balun?

What would be a good reference be for questions like this? The books I have here and Google never seem to have the info I'm looking for.

edwin wrote:
> ... but like to try a full wave antenna 2x 5.17 meters, ...

For maximum gain, you would need an Extended Double Zepp
dipole. It would be approximately 13 meters long fed with
a matching section of 450 ohm ladder-line that is approximately
1.8 meters long. Install ten turns of coax where the coax
connects to the ladder-line. The above lengths would need to
be adjusted, plus or minus, for lowest SWR.

If you really want a full wave antenna, feed it with
approximately 2.5 meters of 450 ohm ladder-line with
ten turns of coax at the coax/ladder-line junction.

Bob D. wrote:
> What impedance would an end-feed infinitely long wire in free space have?

Since you're not in free space, I can tell you that the
characteristic impedance of a horizontal wire over ground is:

Z0 = 138*log(4D/d)

where 'D' is height above ground and 'd' is wire diameter.
The Z0 of #14 wire at 30 ft. is very close to 600 ohms.
Since it is a log function, the Z0 doesn't change very
fast as 'D' and 'd' are varied.

An infinitely long wire would be a traveling wave antenna
with a feedpoint impedance of Z0. However, your 60 ft. long
wire is a standing-wave antenna and the feedpoint impedance
depends upon the phase of the reflected wave.

What are you planning to use as a counterpoise?

Hi Kaz

I have a system for extending WiFi using a Bridge mounted behind the
offset TV dish. That allows me to connect to my lap top thru CAT-5 cable.
As I read it, that wont work for your application. I'd like to learn more
about why the CAT-5 isnt acceptable in some systems.

Source record: 53244

Regarding your very long wire antenna.

Radiation pattern depends on the number of wavelengths that the wire is long. When it is very long, also the propagations speed inside the wire is going to count (some insulation, does slow down the propagation speed of the traveling wave a bit, reducing the far field radiation). Also the straightness of the line is important with very large Le/lambda.

As propagation speed is equal to c, the radiation pattern will be a cone (with side lobes), the longer the wire with respect to wavelength, the narrower the cone will be (so a high directivity). But I believe it is not a useful antenne, the radiation pattern of such a line is not that good and maybe you don't want directivity. When you really want to experiment with long wires at VHF/UHF, a non-linear expanding two wire structure, fed from a balun would give better results. That gives a better radiation pattern (with side lobes). If you would prefer a V-structure, you have to adapt the angle between the wires depending on frequency to get highest directivity (high frequency requires small angle).

The impedance of the single wire antenna shown at the antenna terminal depends on how you feed it. When you feed it from a gradually expanding coaxial structure (launcher), you don't need a balun and get wide band behavior. The "return" conductor is the coaxial structure. When you insulate the wire it becomes a Goubau line (with less radiation).

The impedance of the wire itself is more difficult. The standard formulas are only valid for cross sections much smaller than the wavelength. In your case Mother Earth is not the return conductor.

Your wire is not terminated, so you may expect a reverse traveling wave that cause a cone like radiation pattern in the opposite direction (and of cause reflection into the transmitter).

When you search for traveling wave antenna or surface wave antenna you will find useful information.

Best Regards,

Wim

Jimmie Noserve showed up with his bimonthly Numbers (his period
on?)...still trying to "prove" that Technician class licensees
aren't really no-coders. :-)

Robeson showed up wondering who "Robesin" is...only proving that
the poor guy can't realize it is himself. He always was
illiterate in regards to alliteration.

>Welp, if Fred had a tour in Ohio as an Army recruiter back in the 70s...

Ya know, that always bothered me. Why would an ex-NAVY person
be "recruiting for the ARMY"? [explanation for the trash-mouth
newcomers: Robesin once claimed - in here - that was what his
late father did, but didn't say when or exactly where] The Army
has always used active-duty Army NCOs for such tasks since before
1973 (the ending of the "Draft"). Strange LIE by Robeson, must

have been done at time of some bad goods he swiped out of the Sharps box.

A "Sharps box" is colloquial term for a plastic container (usually wall mounted) for biological waste in medical facilities, sometimes referred to as just a "Sharps." Made by B. D. Sharps company and not affiliated with the dullness of the pro-coders. They can be seen in most doctors' offices and hospitals all over the country.

Robesin is going to come back and say "it's not nice to talk about medical things" as if he is some kind of code caduceus bearing "judge" of medicine. :-) He is a nurse (probably using a wastebasket-salvaged 1983 edition "Physician's Desk Reference" as his medical terminology guide). If he REALLY wanted some REAL rank, he could devote the next 9 years of his life to add MD after his name and honestly say he "saves lives." Tsk, he can't save his own life from the disease of impersonation. May a colony of helicobacter pylori set up housekeeping in his duodenum! :-) [he can share that with papa Fred]

Freddie baby is prolly setting up a spittle session in here bitching and bad-mouthing anyone who doesn't want to relive times past a half-century ago when Kode was King. We'll see what his kind of foaming-at-the-mouth trash talk against "no-coders" will be. :-)

i don't know what 'RG' itself stands for, but the numbers describe different 'types' of cables... not necessarily construction or size.

and no, all rg8's are definately not the same. what type of cable you want to use depends on the impedance, length needed, frequencies to be used, acceptable loss, and also flexibility, weather resistance, and power handling capability for transmitting... and then of course the big factor, cost.

Actually, a full wave antenna has a higher maximum
gain over a half wave by about 1.5 dB.

My 40m full wave antenna has a definite advantage
over a half wave. It works very well on 75m. :-)

"Richard Clark"
> A full wave antenna has no advantage over a half wave.
> It's mismatch is very bad. No BalUn is going to fix that.

The peak, free-space gain of a full-wave linear dipole is about 1.65 dB greater than that of a 1/2-wave dipole. Its center fed impedance is high, but can be transformed at its feedpoint to match conventional transmission lines.

Many AM broadcast stations use a 1/2-wave vertical monopole, which when working against a very good radial ground system constitutes a full-wave antenna. They do it to improve their groundwave field compared to a 1/4 wave monopole, and to reduce nighttime interference to their groundwave by their own skywave.

But maybe the typical amateur operator would not consider these benefits worth the effort.

Jimmie Noserve got hopeless when he tried to be some kind of
"informed insider" into the aerospace business here and his
attempts to "correct" REAL military veterans. He also tried to
foist off his old "$100 rig" as his own design but it was really a
near-copy of the "HBR" series that began in QST years ago.
Jimmie made the mistake of posting on that (relatively new
website) showing his HBR version, the very same photos he
had in a link posted here when he claimed it was all "original."
:-)

>tune which seems way too fast.
>
>Is this information give any more clues to what is going on?

Hmmm.

I had a possibly-similar problem when I tried to use an SGC autotuner with my Kenwood TS-2000. The two don't get along very well - the SGC often fails to achieve a match. This occurs when I use the Kenwood's external-tuner feature (which sends a 10-watt signal), or if I transmit CW or SSB. Sometimes the tuner wouldn't start to tune, other times it would chatter indefinitely and never achieve a match.

The SGC tunes up the same antenna just fine with a Ten-Tec Scout sending 5-10 watts.

I concluded that the problem was likely due to two factors:

- The Kenwood's fixed 10-watt tuning signal is at the low end of the SGC's acceptable range.

- The Kenwood's finals have a power-limiting (or power-foldback) high-SWR protection circuit. As the SGC tried different relay settings with different match-component combinations, and the SWR seen by the Kenwood varied, the Kenwood's power output jumped around... it would reduce power on the higher SWR combinations. This apparently "confused" the SGC - either dropping the power below the level that its SWR bridge was designed to sense accurately, or causing the match-search algorithm to interpret a better match as a worse one.

The tuner worked fine with the Ten-Tec, which doesn't have a power-foldback SWR protection circuit.

Now, as to the rapidity with which the tuner finds a "match" when you change bands, this might possibly be "as designed". Some tuners have frequency-based memory capability, and will re-tune to what they

consider the best-available match without going through a full
match-search.

Doing a fast-match to a 3:1 SWR does seem odd, though.

I have a hunch that the 706 may be running into the same sort of
problem that the Kenwood TS-2000 did - its active high-SWR-protection
circuit may be altering output power in a way which confuses the tuner.

Incorrect! You state "is always" when the proper statement would be
perhaps "has so far been".

But I don't know if that is even correct, because I don't know what the
definition of "sudden global warming" is.

which would be particularly hard

I don't have any 300 ohm twin leed and really(at this time) don't feel like doing the copper pipe thing .Is there another easy way to make one.My thoughts were to maybe take and attach some wires to a board say a 1x4 and just make it work accordingly.It's only for a temporary scanner antenna for in the back yard on my patio. The stock rubber duckie antenna doesn't recieve anything as I'm kinda out in the boonies and an antenna with some gain would work.I tried a magna mount CB antenna and believe it or not it was pulling in signals that weren't even resonant to the frequency it was designed for.
So,in a nutshell there it is. Thanks in advance for any comments or suggestions.
Best regards,
Will

Or maybe nobody wants to talk to him... :-)

>the CW has seen the light that being they betrayed the ARS by listening
>to the ARRL what 50 years ago

I don't think the ARRL "betrayed the ARS". I believe that they
sincerely thought that morsemanship was THEN a topmost skill
of US radio amtaeurs. Fifty years ago would be 1956 and not
long after the passing of ARRL co-founder (and president-for-
life) Hiram Percy Maxim. "T.O.M." used his editorial pages
to promote morsemanship in the 1920s and 1930s.

The original core group of the ARRL were go-getters and smart
enough to realize that, to make enough money as an organization
that came out on top, PUBLICATIONS were the key to survival.
ARRL was first a very small group of local New Englanders,
formed 5 years after the first (and still surviving) national
organization, the Radio Club of America. There were lots of
"national club" competitors in the 1920s but those eventually
dropped out. RCA still exists but is not much concerned with
amateur radio.

Prior to the Internet going public in 1991, the only major
presence for US amateur radio in DC was the legal firm on
retainer from the ARRL. ARRL kept promoting themselves as
"representative" allegedly for the amateur to the FCC but
suspiciously more like a "filter" of amateurs' opinions.
That changed dramatically once the FCC got their website
going and ramped up to take Comments electronically. The
ARRL had to retain a second firm in DC for lobbying.

The evidence is an observation of the number and kind of Comments on 98-143 "restructuring" versus Comments on all those Petitions and last year's NPRM concerning code testing elimination. The pro-code-test advocates' Comments were straight out of the League hymn book about morsemanship with a few adding in nebulous advantages for "homeland security" necessities! [those Petitions began after 11 Sep 01]

What is more telling about the League's stubbornness on their pro-code-test stance is that the IARU took a firm stand on changing the ITU-R amateur radio regulations compulsory (by administrations) morse testing for any license having below-30-MHz privileges...the IARU wanted it OPTIONAL by all administrations (at their discretion) a good year BEFORE WRC-03. The ARRL wanted to keep the compulsory regulation. After WRC-03 the League took a neutral stance, neither for nor against code testing in the USA. It's still a "ARRL versus the World" situation.

>
>yet I do wonder if he isn't Robeson somedays but I am pretty sure he is
>just another bitter old that bought into "incetive Licesning) the brain
>child of the ARRL

It should be abundantly clear that "Incentive Licensing" was never about "advancing" in amateur radio beyond getting TITLE, RAND, and STATUS. That was VERY important to the controlling coterie of the League, folks who wanted to be "better" than others...in a hobby activity.

What "incentive licensing" DID create was just the opposite of "good fellowship" among amateurs, that of CLASS DISTINCTION and a "pecking order" based largely on morsemanship. The morsemen won it. Never mind that radio technology was already far advanced from the 1930s' style of amateur radio and that morse code was falling by the wayside in every other radio service, the League still (stubbornly) held to the belief that all amateurs "should" be able to be morse skilled...even four decades after the 1930s.

The League lobbied for and got the "vanity license" system so that olde-tymers could get their 1x2 and 2x1 super-special guru-status callsigns. Even more status symbolism. Combining "vanity" calls and "incentive licensing" there was a perfect

setup for all who managed to get both to crow and holler they
WERE BETTER than all others. Good fellowship went out the
window...rank, status, title RULED.

>> >Now go bullshit with Dr Death on 11 meters, and don't come back until you
>> >pull your head out of your ass.
>
>> I don't know any "Dr Death," "Slow," nor do I operate on
>> "11 meters."
>
>> Further, you are ten kinds of short on ability to threaten.
>> Your threats and "orders" become recycled electrons doing
>> nothing but dissipating a tiny bit of heat. <yawn>
>
>amasing how they keep resorting to threats and orders

That's all they have left in this new millennium, Mark.

Some of them, such as Blow Code and Hambrecht still think
they are "better than others" in all aspects, not just
morsemanship. They LIKE that. So much so that they are
in great personal fear of losing that very precious rank,
status, title, and privilege that MIGHT happen if the
code test is eliminated. They will LOSE their "better
than you" rationalization. Internally the sky will have
fallen on their self-perceptions.

Personally, I think radio and electronics is totally
fascinating. So much so that I made a career choice of
it while studying for an entirely different sort of
work. Professional work, not some amateur dabbling,
yet I liked to make electronic things in my home
workshop. Things other than work-related tasks. It
is FUN, personally rewarding, not "work."

I got into Big Time HF comms 53 1/2 years ago and have
seen what modes DO work well and on a 24/7 basis on
long-haul circuits that HAD to be kept working. Years
later some KID is trying to "moralize" me into "working
on morsemanship?" He (or she) can go shove it
somewhere...until he (or she) can prove they've done
more than I in radio communications...which they have
NOT done yet in here.

Once, a very long time ago, I thought that becoming a
"ham" was a cool deal. That was before the commsats,
before technology had fully gotten with the semi-
conductor era, before the wonderful way we can get
over most of the world via PCs and the Internet. Why
IS it that some have to be a grand champion of the
1930s over seven decades later? What are THEY trying
to prove? I could care less about 1930s technology

and the "radio standards" of then. I live in the NOW. If some dumbshit wants to moralize about "working" and "investing" he (or she) can go get some flagellation and suffer themselves for their own "cause." I'm not about to join him (or her) in such moralistic self-abuse/mis-use. If these self-styled emperors want to flap their new clothes in my direction, I'll just keep on pointing out that they are NAKED (and ugly).

>just make it work accordingly.

Sure, you can make that work. You'll need to fiddle with the lengths
of the elements, and the attachment point of the coax to the matching
section to get the best match. Using an MFJ or similar antenna
analyzer will make the job easier.

I built a J-pole somewhat like this by taping ordinary insulated
hookup wire to the fiberglass shaft of a bicycle safety flag. It took
a while to get the lengths and feedpoint position adjusted correctly,
but once it was done I had an antenna which was 1.5:1 or better across
the entire 2-meter band, and works very nicely when I ride "bicycle
mobile" at a public-service event.

If you aren't planning to transmit, you probably will have an easier
job of it - your scanner will work acceptably even with a significant
amount of mismatch at the antenna feedpoint.

I'd suggest thoroughly waterproofing whatever piece of wood you use -
treat it well with marine spar varnish or a similar outdoor-rated
polyurethane or other varnish. This will ensure that the wood doesn't
soak up rain moisture and change its electrical characteristics and
de-tune the antenna.

As another alternative, since you're scanning and would presumably
prefer a wide antenna bandwidth, would be to make yourself a skeleton
discone. A chunk of wood with holes drilled in it, and a dozen pieces
of stiff wire, and a bit of simple soldering and you'd end up with an
antenna which would probably receive acceptably over a very wide
bandwidth.

3628. FREEWARE - WinCAP Wizard - VOACAP

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-03 20:17:02 UTC
From: J Tabor <denews@taborsoft.com>
Message-ID: <12fme21scbre731@corp.supernews.com>
Source record: 53265

Greetings,

Our last invitation post was 14 Feb 2006. This one is similar but includes new information and an extra-special offer.

What is WinCAP Wizard? WinCAP Wizard is the most powerful HF Communications Analysis Prediction package ever developed.

Please understand I'm typically a humble type fellow. Unfortunately, if this message isn't compelling, you will likely ignore the tool and miss the offer. Good products do indeed sell themselves. But obviously, folks must first try the product. In a vast sea of amateur radio related products and tools, here is a tool you will probably like and, find very useful. Sure, you have product X, have used it for years and know it well, plus you are busy and don't have time to learn a new tool. But, does this logic keep you from acquiring new hardware, like radios, antennas and computers? Of course not.

You want free software; all of our software now defaults to freeware and provides basic functionality, sufficient for many users. The default WinCAP Wizard v4 download is known as QSL-ware. QSL-ware basically means freeware. <G>. We do appreciate an email acknowledgement and comments - thus our term QSL-ware.

This QSL-ware version provides unlimited point-to point and NCDXF beacon predictions. The extensive "Location Browser" provides a prefix search along with other useful information. The unique "Beacon SmartChart" and the Smart-Map-Geographic View are in this basic feature set. There are 2 point-to point charts and 3 beacon charts, each with numerous options, 4 point-to point reports and 4 beacon reports - all free.

The registered version adds a lot of tools and functionality. The "Coverage-Analysis View", is an elaborate map with the ability to plot any of 7 parameters, for up to 9 frequencies and all 24 hours. View any hour and frequency for each predicted parameter with a mouse click. More? A DX-list plot and search are provided. The Coverage-Analysis View provides several additional unique features.

Also included in the registered version is the "User Batch" prediction type. With the ability to analyze up to 18 unique circuits and present the results with 5 charts and 3 reports our user batch mode is both powerful and flexible.

Special user-batch prediction "views" provide definite advantages for the contest-oriented op. The Contest-Plan SmartChart and Contest-Plan SmartReport deliver incredible insight into "when to be where" during the contest. These could also be useful to the savvy DXer.

Sorry - I can't list all the advantages here - this is already too long. But if all this isn't enough, the registered WinCAP Wizard package includes GeoAlert-Extreme Wizard and Beacon Time Wizard, as a free bonus.

A 60-day full trial key is available upon request. Try the software tools. If you don't think them worthy of being paid for, they revert back to the default QSL-ware/freeware mode and functionality, without time limit.

Is there any question WinCAP Wizard is the leader in the HF propagation prediction category? If so, that thought should soon be wiped away. The next major version, v5, is due for release very soon. As we say, the best keeps getting better. <VBG>

Before a brief introduction on the main features of the new version, the special offer. Register v4 now and qualify for a free upgrade to v5.

WinCAP Wizard v5 provides a "Contest-Log Manager" and imports Cabrillo format logs from 55 different HF contests; more contests can be added easily, upon request. The logs can then be plotted to the "area coverage" map view - with or without predictions. The logs can, of course, be filtered and plotted by day, band, hour and any combination of these.

To my knowledge no other software exists to geocode calls for stations worldwide. There may be software that plots US, and even Canadian, calls. Do you know of any? Are you interested in this functionality? Can you imagine the possibilities?

The v5 prefix search features are among the finest available. The QSL-ware version also benefits - through the Location Browser.

Both USA and Canadian call lookup is provided. The primary purpose is log station geocoding but the ability is "way cool" and proving interesting. <G> For example, using the prefix/call search on the area-coverage view, you can begin typing a call and the great-circle path is plotted; as you continue typing, the great-circle plot changes to show the prefix and - as you complete the call - the actual location is plotted.

There are other minor enhancements over v4. The new WinCAP Wizard v5 provides an extensive set of powerful tools. Hopefully users will be able to easily do complex and interesting comparisons -that previously were too labor intense and time consuming.

Still, if you use a competing tool, not to worry, they can surely add a few of our choice features. <VBG> But it's doubtful they can add them all.

In any case, you are invited to download and use WinCAP Wizard version 4 in the QSL-ware mode without time limit. You will also find several other useful amateur-radio related software products at www.taborsoft.com

Don't miss the ID Wizard freeware. It provides a rich set of useful "tools".

Thanks for reading this far. Hope to work you in a contest.

Cheers,
KU5S

Gentlemen, The regulations at the patent office used to accept a
declaration for a patent claim if the claiment produced a written
description of his invention which was also signed and dated by another
person who stated that he had read it and understood its content, this
document gave the claiment to claim rights over all those that follow
that disclosure.
I seemed to remember that the PTO changed things with respect to how
they will deal with future claims where applications would be printed
to the World when received. Did this have any affect with respect to
the presigned declaration alluded to above?
Any info would be appreciated especially if claims presented to the
patent office provides
seniority over pre dated signed claims that have yet to be forwarded to
the PTO
Regards
Art

The FCC thought so too - well into the 1970s.

> Fifty years ago would be 1956 and not
> long after the passing of ARRL co-founder (and president-for-
> life) Hiram Percy Maxim.

Maxim died in 1936. 1956 was twenty years later.

> "T.O.M." used his editorial pages
> to promote morsemanship in the 1920s and 1930s.

He also promoted many other things on those pages, such as technical progress, operating skills, public service, and the observance of government regulations.

> The original core group of the ARRL were go-getters and smart
> enough to realize that, to make enough money as an organization
> that came out on top, PUBLICATIONS were the key to survival.

Publications were one way to support the organization. They also supported amateur radio by offering low-cost information specifically for the radio amateur.

> ARRL was first a very small group of local New Englanders,
> formed 5 years after the first (and still surviving) national
> organization, the Radio Club of America.

But it didn't stay that way for long. By the time of the 1917 shutdown - just three years after ARRL was founded - it was a national organization.

One of the cofounders, Charles H. Stewart, 3ZS, lived right here in Radnor, PA. Hardly "local" in those days.

> There were lots of
> "national club" competitors in the 1920s but those eventually
> dropped out.

Name some.

> RCA still exists but is not much concerned with
> amateur radio.

It is a very small organization whose main activities seem to be
honorary and historical.
>
> Prior to the Internet going public in 1991, the only major
> presence for US amateur radio in DC was the legal firm on

There was nothing to stop others from doing the same thing. Nor from
contacting FCC directly.

> ARRL kept promoting themselves as
> "representative" allegedly for the amateur to the FCC but
> suspiciously more like a "filter" of amateurs' opinions.

Why are you suspicious, Len? Anyone could petition the FCC directly,
and many did, long before the Internet and ECFS.

> That changed dramatically once the FCC got their website
> going and ramped up to take Comments electronically. The
> ARRL had to retain a second firm in DC for lobbying.

All ECFS did was to make it easier to petition and comment.

Back in the 1960s, when the changes known as "incentive licensing" were
being debated, FCC received over 6000 comments from individuals and
groups. There were at least 10 proposals besides the ARRL's. Those
other proposals were taken seriously enough by FCC to get RM numbers.

> The evidence is an observation of the number and kind of
> Comments on 98-143 "restructuring" versus Comments on

> were straight out of the League hymn book about morsemanship
> with a few adding in nebulous advantages for "homeland
> security" necessities! [those Petitions began after 11 Sep
> 01]

??

The fact is that the majority of individuals who commented supported
the retention of at least some Morse Code testing. The majority also
supported elimination of the Morse Code test for the General Class
license.

> What is more telling about the League's stubbornness on their
> pro-code-test stance is that the IARU took a firm stand on
> changing the ITU-R amateur radio regulations compulsory
> (by administrations) morse testing for any license having
> below-30-MHz privileges...the IARU wanted it OPTIONAL by all
> administrations (at their discretion) a good year BEFORE

> WRC-03. The ARRL wanted to keep the compulsory regulation.

Not true! Not true at all, Len.

The fact is that way back in 2000 or 2001, the ARRL BoD changed their policy wrt S25.5. They decided to neither support nor oppose changes to ITU-R S25.5.

Given the strong support from many other member countries to change S25.5, the ARRL's no-opinion policy pretty much guaranteed there would be majority support to change S25.5.

> After WRC-03 the League took a neutral stance, neither for
> nor against code testing in the USA. It's still a "ARRL
> versus the World" situation.

Wrong again, Len!

In ARRL's petition to FCC, they proposed eliminating the Morse Code test for General but retaining it for Extra.

The majority of individuals commenting on the NPRM wanted the test eliminated for General.

The majority of individuals commenting on the NPRM wanted the test retained for Extra.

The two majorities are not composed of all the same individuals, but they *are* majorities.

> >> >> Thank you, Rick! You spoke volumes of reality in this new

"RAND"?

Do you mean Remington Rand, Ayn Rand, or the South African monetary unit?

> That was VERY important to the controlling
> coterie of the League, folks who wanted to be "better" than

> others...in a hobby activity.

Nope. That's not what it was about at all, Len. Do try to get your history straight.

The fact is that the "incentive licensing" changes were an attempt to *return* to a system something like that which existed before February 1953. The complexity of the final result was due in large part to it being pieced together from the numerous non-ARRL proposals mentioned earlier.

btw, the 1951 restructuring that gave us the license classes with names rather than letters was not primarily driven by ARRL.

> What "incentive licensing" DID create was just the opposite of
> "good fellowship" among amateurs, that of CLASS DISTINCTION
> and a "pecking order" based largely on morsemanship.

How so?

Did you forget about the written tests?

> The
> morsemen won it. Never mind that radio technology was already

> all amateurs "should" be able to be morse skilled...even four
> decades after the 1930s.

How many other radio services used Morse Code in 1966, Len?

Was there a shortage of trained radiotelegraphers during the Vietnam War?

> The League lobbied for and got the "vanity license" system so
> that olde-tymers could get their 1x2 and 2x1 super-special

>
> Some of them, such as Blow Code and Hambrecht still think
> they are "better than others" in all aspects, not just
> morsemanship.

Well, maybe they are, Len. Or maybe they aren't.

Why does it bother you so much?

Do you have a need to look down on everyone?

> They LIKE that. So much so that they are
> in great personal fear of losing that very precious rank,
> status, title, and privilege that MIGHT happen if the
> code test is eliminated.

How will any currently licensed amateur lose anything if the Morse Code test is eliminated?

> They will LOSE their "better
> than you" rationalization.

How?

If they really are better than you, they'll still be better without the test. And vice-versa.

> Internally the sky will have
> fallen on their self-perceptions.
>
> Personally, I think radio and electronics is totally
> fascinating.

Me too. Amateur radio particularly.

> So much so that I made a career choice of
> it while studying for an entirely different sort of
> work.

Funded by the taxpayers, too.

> Professional work, not some amateur dabbling,
> yet I liked to make electronic things in my home
> workshop.

Does being paid for something make someone automatically "better", Len?

> Things other than work-related tasks. It
> is FUN, personally rewarding, not "work."

But not rewarding enough for you to get an amateur radio license, it seems.

Or have you gotten that Extra out of its box, as you told us you were going to do, way back on January 19, 2000?

> I got into Big Time HF comms 53 1/2 years ago and have
> seen what modes DO work well and on a 24/7 basis on
> long-haul circuits that HAD to be kept working.

Using equipment supplied and paid for by others. With a team of several hundred people trained to do the job.

That doesn't make you more qualified to judge what amateurs do - self-funded and largely self-trained.

> Years
> later some KID is trying to "moralize" me into "working
> on morsemanship?"

Is youth somehow wrong, Len?

> He (or she) can go shove it
> somewhere...until he (or she) can prove they've done
> more than I in radio communications...which they have
> NOT done yet in here.

I see.

What if someone older than you, with more radio experience, told you that you should work on your morse code skills? How would you react?

> Once, a very long time ago, I thought that becoming a
> "ham" was a cool deal. That was before the commsats,
> before technology had fully gotten with the semi-
> conductor era, before the wonderful way we can get
> over most of the world via PCs and the Internet.

What about your posting of January 19, 2000?

> Why
> IS it that some have to be a grand champion of the
> 1930s over seven decades later? What are THEY trying
> to prove? I could care less about 1930s technology
> and the "radio standards" of then. I live in the NOW.

Then why do you tell us so much about your past?

btw, if you are *not* interested in becoming a ham, why are you so vocal about the requirements?

> If some dumbshit wants to moralize about "working" and
> "investing" he (or she) can go get some flagellation
> and suffer themselves for their own "cause." I'm not
> about to join him (or her) in such moralistic self-

You sure seem to spend a lot of effort arguing about it, though.

Why?

> If these self-styled emperors want to
> flap their new clothes in my direction, I'll just keep
> on pointing out that they are NAKED (and ugly).

Perhaps they are simply holding up a mirror.....

Gee, Len, it's been more than three years since the ITU treaty changed.
Some countries have eliminated Morse Code testing, some haven't, and at
least one (Canada) has worked out a unique solution to the debate.
Meanwhile the USA rules on the subject haven't changed since 2000.

Are you frustrated because your will has not become law...yet?

Gee, Len....do you think posting that way will cause people to change
their minds and agree with you?

Do you think FCC would be convinced by such arguments?

Is that sort of posting your idea of how a "professional" behaves?

Hi Mike,

That won't work. One of the leading "conservatives," Richard Perle,
was an aide to my state's Democratic Senator, Scoop Jackson, who stood
politically just a few feet to the left of Hitler and Stalin (even
Roosevelt's administration referred to us obliquely with "the 47
United States and the Soviet of Washington").

Let's face it, the administration has abandoned the church's teachings
that we are the stewards of creation. Instead, the apocalyptic
message from these nihilists (another Russian hallmark) is nothing
matters because there's not much time left anyway. Such is the belief
system of the neo-cannibals.

>
>BTW, what does the RG number signify anyway? The size? The construction?

Cables advertised as RG8 should have similar characteristics, though
the market contains sub standard products, and variants (eg foam
dielectric).

RG8 (or more commonly used RG213 which is similar in characteristics)
is quite lossy at 70cm, and you might not find its loss acceptable,
depending on the length of your run and your own requirements.

For example, the loss on 30m of Belden 8267 (RG213) at 440MHz with a
load end VSWR of 1.2 is 4.8dB, about two thirds of your transmitter
power is lost in the cable. 9913 is a little better at 2.7dB, LDF4-50A
at 1.4dB. Try your own scenario at http://www.vk1od.net/tl/tllc.php .

If you think RG8 is stiff and expensive, you don't seem to have much
experience of UHF. If you are more familiar with RG58C/U, it has a
loss in the above scenario of 12dB, 6% efficiency, but it works for
some.

Re what is RG anyway? Google for info on the RG scheme, try searhing
for "Radio Guide".

: >thoughts were to maybe take and attach some wires to a board say a 1x4
and
: >just make it work accordingly.
:
: Sure, you can make that work. You'll need to fiddle with the lengths
: of the elements, and the attachment point of the coax to the matching
: section to get the best match. Using an MFJ or similar antenna
: analyzer will make the job easier.
:
: I built a J-pole somewhat like this by taping ordinary insulated
: hookup wire to the fiberglass shaft of a bicycle safety flag. It took
: a while to get the lengths and feedpoint position adjusted correctly,
: but once it was done I had an antenna which was 1.5:1 or better across
: the entire 2-meter band, and works very nicely when I ride "bicycle
: mobile" at a public-service event.
:
: If you aren't planning to transmit, you probably will have an easier
: job of it - your scanner will work acceptably even with a significant
: amount of mismatch at the antenna feedpoint.
:
: I'd suggest thoroughly waterproofing whatever piece of wood you use -
: treat it well with marine spar varnish or a similar outdoor-rated
: polyurethane or other varnish. This will ensure that the wood doesn't
: soak up rain moisture and change its electrical characteristics and
: de-tune the antenna.
:
: As another alternative, since you're scanning and would presumably
: prefer a wide antenna bandwidth, would be to make yourself a skeleton
: discone. A chunk of wood with holes drilled in it, and a dozen pieces
: of stiff wire, and a bit of simple soldering and you'd end up with an
: antenna which would probably receive acceptably over a very wide
: bandwidth.

The skeleton discone sounds like a neat idea.Do you have a diagram or
something for that? Oh BTW I am a ham I am just working with limited
resources at the moment. Call hre is Kilo Alpha 3 Victor India Delta . Nice

to make the aquaintance.

Ay up m'duck

I have been absent for some time from this group but now have received
the sad news
Reg was a rascal no doubt and engaged in many contraveries at the Rose
and Crown
or what ever was configured on the brass mitifs of the delivery horse
Knowing how Reg thought I suspect that he kept his black country accent
to the end where he would delight in those that thought with such an
accent could not possibly be one of an educated.person.
As an old timer from the East End of London and later from Nottingham I
know the difficulties of pursuing education when at the age of fourteen
one left the school yard for the mines or any way to make a living. Yet
Reg somehow overcame a lot of fences at that time and not only made it
but made it with distinction. This is a special day where englishmen
reflect upon a similar day in '39 when people were fully aware that in
the corner of all battlefields there lies a piece of England and
frankly Reg has done us all proud in what he has achieved in life and
no doubt is now debating those who were waiting for him. At this time
you will take more than one look at men who simply look like him in a
searching manner but the true realisation will come when you will stand
tall again and relish in the recall of old times. Dads do pass away as
mine did but his style of living affected how you lived and will live.
I will miss Reg even tho I was anoyed at him many times but always
drawn to what he had to say about the hobby.
I send my best wishes to all the family where all should be told that
tho he may well have left us what he had to say is indelibly written in
many parts of the World
Cheers and beers

UP/DOWN, CHARM/STRANGE, TOP/BOTTOM ... Gosh almighty!

Are Quarks really matter? Or highly concentrated clusters of energy? Do they have mass independent of energy? or, Wavelength?

How would Heisenburg know anything about them?

I think it is time to name a new computer controlled radio TOP/BOTTOM. Wouldn't that be CHARMing? It would certianly be STRANGE!

Trees cause polution /??????? You're kidding, I hope!!

Trees are the solution to CO2 and global warming. Their process is: CO2 in, and O2 out.

Now, fish life cause Methane; along with refried beans!

Now to replace the depleted Ozone layer we need more thunderstorms. Lightning produces an 3O2 to 2O3 reaction. We should all have a Van DeGraff generator in our back yards to contribute to the replenishment of the O3 layer.

Hydroplants that produce electricity add Nitrogen to the downstream H2O and that's bad. So, we better shut down the Hydro plants. Fission facilities are used to produce electricity but they produce long half life waste material. So, we better shut down the fission facilities. The carbon [oil/coal/coke] facilities produce SO2 and CO2 products. So, we better shut down the carbon power plants. Without that power we can't turn on our computers. So, we can all go back to talking on the real radio ... sorry, no electricty ... no radios. We add a generator to ur bicycles and get in shape while we make electricity. Wait! Wait! Wait! can't do that! Exercize increases CO2 gases when we exhale. Looks like we have to stop exhaling!

If we can't exhale we better not inhale! And if we can't inhale who gives a damn about trees and pollution!!

Ed, most CB users have vertical antennas and your dipole will be
horizontal and this is not good. You may be better off making a 5/8th
ground plane.

I always wanted to try a simple 11 meter dipole mounted vertical to see
if it would really work. Anyone ever tried one?

There is a low impedance feedpoint for a full wavelength 11 meter antenna.
Simply feed it 1/4 wavelength from the end and add an RF choke to the feedline.

```
------------------------------||----------
||
3 X 2.58 meters || 2.58 meter
feed point
```

Cecil can tell you the feed system details.

Sorry, some trees do cause pollution.

Some trees produce huge amounts of isoprene, notably oak.

Some trees produce nitrogen oxides, notably pine.

Every wonder why the Blue Hills of Kentucky and Blue Mountains in
Australia are that way? Hydrocarbon pollution from trees.

Google for it.

>Greetings Ed
>

Ed,

You are collecting the full range of answers here which must be a
little confusing.

It seems that you are talking about horizontally polarised antennas.
That might be a disadvantage if you were working local stations using
vertical polarisation, less a worry for ionospheric paths or where the
other station is also horizontally polarised.

The full wave dipole does have a little gain in some directions, but
understand that power is not created in the antenna, the higher gain
antenna just distributes the energy more in certain directions. The
gain in some direction(s) is at the expense of less gain in other
directions. (BTW, the gain is so little that you are unlikely to
notice it.) Depending on what you want to use it for, the gain /
pattern of a full wave dipole might not be on average better than a
half wave dipole, or an omnidirectional antenna. Indeed, some
omnidirectional vertical antennas might be better for certain
applications.

Richard is right in telling you there is not much in it (though he may
have been a little more emphatic), but centrefeeding a full wave
dipole is a small challenge, but possibly beyond your knowledge and
experience. You can offset the feedpoint, but it is not an ideal
solution either, it that has its disadvantages (skewed pattern, Z<>50,
feedline coupling because of asymmetry).

If the stuff of antennas is interesting, perhaps you should consider
pursuing an amateur licence?

Owen

>to make the aquaintance.

Take a look at the discussion at

http://www.radioreference.com/forums/archive/index.php/t-8000.html

You'll see a bunch of different homebrew discone designs there,
including both traditional (solid sheet-metal disc and a sheet-metal
cone) and skeleton (radial rods to make both the disc and the cone).

The Diamond D130J is a commercial version of the latter.

One simple way to put together a discone "on the cheap" - use a block
of wood perhaps 2" in diameter and 2" high as the center insulator.
Drill a 3/4" hole in the center, insert a piece of 3/4" dowel (the
mast) and glue into place. Take 3 or 4 pieces of stiff copper wire
12" long, twist them together in the center, and the ends apart so
that they form a flat disc of radial-like elements, solder the twisted
section together, and mount on the top of the wood block with a couple
of wire staples. Drill a set of 8 holes, angled upwards into the
block at a 45" degree angle, and insert 12" wires or rods (forming the
skeleton cone). Run a length of bare stranded wire around the inner
ends of these wires or rods (right where they enter the block) and
solder. Drill a hole upwards through the block, right beside the dowel.

Now, run your RG58 (or whatever) feedline up the mast/dowel and
zip-tie it into place. Remove a few inches of insulation, separate
the braid from the center conductor, strip the end of the center
conductor, run the stripped end up through the small hole you drilled
and solder it to the junction of the six radiating spokes, and solder
the coax braid to the wire which connects to all of the skeleton-code
wires. Waterproof the end of the coax somehow (paint-on electrical
"tape", perhaps).

You now have a garage-built skeleton discone, akin to the Diamond D130
but a lot less expensive. [Probably a lot less rugged, too, but if
it's just a temporary it should serve you well enough.]

I just picked up 200 ft of rg8 at radio shack for 40 bucks. 10 bucks for 50 foot run. Anyways, there was a website I came across recently that showed the swr rating of different size rg cables based on band. I searched for rg8 and the site popped up. It was complete with charts, etc. Very nice. It only takes a few minutes to find if you don't mind trudging through the sites.

You really don't know for sure unless you measure it. Not a big deal
if you've got a dummy load and a in-line watt meter.

RG-8 is a type not a specification.

I don't know what kind of cable Radio Shack is selling for that price, but
it must be very poor quality. Probably 5 times the loss of any quality rg-8
size cable at 2 meters and above. RG-8 size cable of any type should be
atleast $ .50 per foot and more like $ .75 per foot or more.

There should not be any tables for SWR for differant cables based on the
band.
Maybe you mean the loss in dB instead of SWR.

What's an SWR rating? The cable with the most loss will have the best
SWR when feeding a mismatched load.

They just want to be appliance operators Fred, they don't care if they
can't commute. They want to pick up a microphone and start gabbing. A ham
license means nothing to them, and will mean even less if ham radio tests
are dumbed down more.

It was a close out special at $10 per 50 feet. I had to hit two stores before I found any, a Ham who was working at the first RS store had bought out all that his store had in stock. I bought a 100 feet at that price at the second store. I also have a 50 foot section of some of their RG-8 stuff I bought 20 years ago for SSB CB use (yes, I once was wooed by the dark side). Can't tell any real difference on HF frequencies when using the old RS RG-8 or some new RG-213 I got from Texas Towers.

I don't understand. Are you claiming that the earth is NOT warming?

BTW, I, for one, do not agree with the argument that if GW is cyclic,
that human activity is not involved or is not important to it.

(I HOPE Cecil was kidding about the campfire theory of the last cycle.)

If the posters in this NG are really going to spend time refuting the
veracity of GW as a phenomenon, I'm pretty disappointed.

Antennas, anyone?

Hi, I have used telescopic fishing poles (known as crappie poles) for
many years on HF yagis. You can obtain them on E Bay quite cheaply upto
twenty feet long but in 4 foot sections.These are easily covered with
sticky back aluminum foil obtainable at any hardware store. Also
available is aluminum tape that has a backing of glass cloth. Advisable
to add aluminum tape after rod is extended as pretaped sections become
difficult to assemble. I have broken some over the years during
experimentation but with various sections on hand it is a quick turn
around to get back on the air. I once put 13 of these elements on a
boom with no problem regarding weight and it appears they are made of a
black fiber type material and ofcourse hollow As an aside sections have
a standard taper such they cannot be pulled apart at the ends and no
clamps needed.These are especialy easy to carrywhen hiking.
Regards
Art

I am trying to build a 20meter 1/2wl end fed vertcal antena and havent had a lot of success. The antenna is for use at maximum legal power so I need componets in the network that will hold up. I have tried a J pole configuration that I never was able to properly tune and I have tried lump sum LC values that melted down with max power. I guess the last way is doable but not unless I want to spend really big bucks on new HV capacitors. I was thinking about the matching section on my Ringo Ranger. Why not just scale this up for 20M? The mechanics of it arent a real problem, I can fabricate most anything I would need. Seems like I've heard the mast for a Ringo needs to be at least a 1/4 wl long, is this true?

Back in the early 80s I briefly worked for a cable company that rented space on power poles. I think someone told me that it cost the cable company 2 dollars a year per pole.The power companies should have continued along this line by istalling fiber on their poles and renting out he fiber and the poles.

It wouldn't hurt my feelings to see Radio Shack continue to downsize other than the people losing their jobs. That always is a bad situation but the company has forgotten what made it a growing company. I remember years ago being able to go into a RS store and get practically any electronic part within reason and actually talk to someone with enough technical knowledge to know what it is and what it does. Like the rest of corporate America, they have eliminated the jobs of the knowledgeable so they can pay dolts a bit more than minimum wage.

One of the basic components of coax cable is the design of the outer shield. The measure of that shield is optical coverage. Cable is available with optical coverage that ranges from <80% to >95%.

The optical coverage contributes to the shielding effectiveness and losses through the cable shield, leakage inductance.

A quick test of shield design is the remove about 1 inch of jacket and inspect the shield . A tightly woven shield with a lay angle of close to 45 degrees will have excellent optical coverage.

In the past, RS cable had optical coverage in the 75 to 80 percent range.

You know, I've now read so many of these RS slams...and, I suppose, they are mostly accurate. However, they are true due to the nature of a failing business model. That model tried to keep part of the business catering to the electronics experimenter. (You CAN still get caps, resistors, etc. there.) Their failure comes, in part, out of this desire to appease the very people who deride them for it.

I bet I've been RS 4 times in a month, each time buying $10 or less in supplies. Who can pay the rent on such purchases?

Hasn't anyone seen the same thing happen to hardware stores?
The "good old days" of a knowledgeable hardware man spending more than 5 minutes with you to sell a 50 cent item are also mostly gone. The biggest difference is that hardware stores-of-old lost out to the "big box" hardware warehouses. If RS goes (and it probably will), there is no alternative to the electronics experimenter other than the internet.

In my area, at least, there are no components, circuit boards, solder, etc in the "big box" stores.

Maybe the rest of the stuff they sell is crap...now it's the same crap you can get at WalMart.

I, for one, will miss RS if it goes. In fact, I have a bit of a soft spot for RS because that's where I got started getting interested in ham radio. Has it changed over the years? You bet. Why not get out an old picture of yourself and look in the mirror. Have YOU changed?

The Wireman's Wirebook IV gives a pretty good history of coax: Going
back to the 1940s, R = Radio Frequency; G = Government; 8 is a
sequential number assigned for government approval, thus RG8/U with U
= Universal Specification.

That said, all of these terminologies are fairly obsolete to the
modern manufacture of coax, according to the Wireman.

Oh no, just the opposite.

My point is that when the CO2 percentage of the atmosphere goes up,
more heat is retained. If the increased retention of heat does not
increase the surface temperature of the earth, then something is
happening to keep that from happening.

I have yet to see an attempted debunking of global warming that is not
political in nature.

Careful, careful, Mark...Sister Nun of the Above, now the
Mother SUPERIOR is BACK, ruler in hand, ready to spank the
knuckles of anyone who DARES say anything negative about
the blessed, sacred ARRL!

I was literally going back 50 years to 1956 and remembering
how both the electronics hobby and the (much, much bigger)

electronics industry was doing...preparing to move to
California and the aerospace industries that year. Frankly,
the ARRL wasn't keeping up with the electronics industry
other than keeping QST afloat with advertising revenue.
Since they were largely unaware (from their publications)
what the (then) long-haul radio communications were doing,
they couldn't really decide which way to go for amateurs.
Their decisions were based largely on ignorance, especially
that of SSB. The commercial-military folks on HF were already
USING SSB on HF and had been doing it for over two decades by
1956...yet the ARRL wanted amateurs to believe that "amateur
radio 'pioneered' SSB." :-) Bullshit.

>> >yet I do wonder if he isn't Robeson somedays but I am pretty sure he is

>be a publicly accsable (except on an ARS wide) basis

Well, it's a subject which is damn clear to outside observers
but the Believers are about to strike a blow for the Church of
St. Hiram. Mother SIPERIOR is back in her habit of
one-liner sentences thinking she can slay the dragons (of her
mind) which defile the sanctity of the Newington folks who
"know what is good for amateur radio!" :-)

Prior to 1990 there were already FIVE different license classes
in US amateur radio. The no-code Technician class made it SIX.
A decade later the FCC chopped that in half. Rightly so in my

estimation. It had gotten literally Byzantine in structure with
the privileged bandplans and who could use what mode. It was
worse than the commercial-professional operator licenses. The
Restructuring was sorely needed for the avocational activities.

The worst blow to the rank-status-title morsemen was cutting
the code test rate down to a single, low one, well below the
exhaulted, royal rate of 20 WPM that they overused for
bragging rights before 1998. :-) Those extra super special
morsemen lost NO PRIVILEGES ON THE BANDS but the sky fell in
on their bragging rights. Boo-hoo, poor morsemen. :-)

>and inccreasingly cold and unfeeling and failing to fufill the debt
>they owe to those that came before them

I disagree with you a bit...nobody "owes" anything
other than bill payments, Mark.

The rabid amateur morsemen are just full of themselves.
They have lost their ability to RULE by that singular
skill, are now worried that they might lose all their
rank, title, status, and privileges when the code test
is finally eliminated. Few of them seem to have much
for themselves beyond that bragging right. <shrug>

That is EXACTLY what I tried less the relays. Problem is I dont have good enough caps for full power and probably will not get any. I am trying to make do with what I have. It worked fine with 100 watts. I am considering lengthening the antenna to 5/8 wl. This should give me a lot less voltage at the feedpoint and I shouldnt even need a capacitor. I did like the idea of dual band antenna .

That was my first thought and I invisioned 16 ft of open wire line runing
out across the yard. But now that I think of it this may be a workable
solution. No reason it has to be stretched out straight, circle it around
the antenna. Hmm back to Ringo again.

The matching section for your 20m 1/2WL monopole can
be mounted horizontal if it is more convenient. FP
is where it connects to the 1/2WL vertical section.

```
+-----------X-----------16.5'---------------+FP
|
+-----------Y-----------16.5'----------------open
```

The coax connects at X and Y where the 50 ohm feedpoint
is located. #14 or larger wire will handle anything
legal that you can put into it. No high voltage capacitors
required. No lossy coils required.

Just use a regular CB antenna. It will work fine. I had one of these radios years ago and used a little center loaded CB antenna that was just about 2 feet long I got from Kmart. Not a great antenna for CB but I could pick up 3 or four NOAA stations in the area. Even a full size CB antenna will work well with it. A discone antenna can be modified to work on both the NOAA frequencies and CB equally well by extending 3 of the rods that make the skirt of the antenna to 1/4 wl at CB freq and adding another1/4 wl section that extends vertically from the disk.

Have you tried using coax for the caps, same as the cushcraft ringos?
I'm not sure how much power a cap made from say 213 would handle,
but it going to be several hundred watts at the min.. I've built what
you
are building. It will work fine, and the height above ground is not
that
critical. But I eventually changed the antenna to be a 40 GP and a
5/8 GP for 17m. I used a relay to switch the loading coil for 17m
in/out.
The "gamma loop" for 20m is kinda large, so you need some stiff tubing
to hold stable. IE: copper tube, etc..

I came across the KE2QJ antenna matching network for HF mobile
operation in the 2004 ARRL handbook and it looks interesting.

It is designed to match a vertical whip which is not loaded itself,
and uses a lower value coil at the base and theoretically should
result in higher efficiency than the conventional loading method.

Does anyone have any experience with it?

Thanks Cecil This was my first plan but I dont have room to run the stub straight out so I kind of tabled the idea for a while. Now that I have thought about it there is no reason I couldnt wrap it around the antenna. Talking with others sure helps the thought process. I still may play with the idea of the 20M Ringo design. It would be a lot of fun telling people you have a 20M Ringo Ranger. My only real problem with using the Ringo style matching network is that I heard once upon a time that the Ringo utilizes the mast as part of the radiator. The main thing I see the Ringo type match has going for it is that it would be about half the size of a 16.5 ft stub wrapped around the antenna

C'mon Cecil, you know the advocates of GW deny it is a natural phenomena.

Just wait until the next ice age, even a minor ice age, then they, the GW advocates, will be demanding more CO2 in the atmosphere. :-)

3706. Is antenna a transducer to 377 ohms?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-04 19:36:00 UTC
From: David <nospam@nospam>
Message-ID: <Z72dnY4YWLuVH2HZnZ2dnUVZ8qKdnZ2d@bt.com>
Source record: 53095

The impedance of free space / air is said to be 377 ohms. Impedance is ratio of E/H. The feedpoint impedance of an antenna is usually 50 or 75 ohms.

Can an antenna ever be regarded as a transducer that transforms a radio wave from 50 ohms to 377 ohms i.e. provides an impedance transformation? With a long tapered antenna, the feedpoint is at 50 ohms. Is the end of the antenna at 377 ohms to launch the wave easily into free space? In this case, antenna is a travelling wave antenna e.g. broad bandwidth biconical. Does the impedance gradually change from 50 ohms to 377 ohms over the length of the antenna?

The impedance of the end of an antenna (open circuit), where it is a high voltage point, is usually 5K or 10K ohms.

For those of us who don't have the 2004 ARRL Handbook,
could you describe the theory? If it is based on the
old wives' tale that the current through a loading coil
is constant, it is all wet.

3709. Dipole with standing wave - what happens to reflected wave?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-04 19:44:17 UTC
From: David <nospam@nospam>
Message-ID: <HfKdnV6Ks7RkHmHZRVny1Q@bt.com>
Source record: 53098

RF transmitter output has impedance of 50 ohms and is connected to dipole with a feedpoint impedance of 50 ohms via feeder with characteristic impedance of 50 ohms. System is perfectly matched. I expect SWR meter to show perfect match of 1:1.

Dipole has a standing wave on it. Ends of dipole are at high voltage. Dipole is centre-fed with centre being high current point. Standing wave means that a reflected wave exists. Wave is reflected from open ends of dipole. What happens to the reflected wave? How does it vanish at centre of dipole? Why does reflected wave not go along feeder into transmitter output? There cannot be a reflected wave on feeder because SWR is 1:1.

There's no reason why you couldn't spiral it around
the antenna like a pancake inductor. If you kept each
spiral about a foot away from the next one, the area
occupied would be pretty small. Good luck.

The feedpoint impedance of a resonant standing wave
antenna is a result of interference/superposition and
is a virtual impedance equal to

(Vfor-Vref)/(Ifor+Iref)

The characteristic impedance of a standing wave antenna
is actually several hundred ohms.

If the reflection is exactly in phase with the next wave arriving
through the feed line, then it just raises the impedance the line
sees. In other words, the reflection acts as a large part of the feed
energy for the next cycle. It doesn't bounce into and out of the feed
line, it bounces back and forth from end to end of the dipole.
Actually there are two reflected waves going in opposite directions,
end to end, simultaneously.

If the feedpoint impedance of a dipole is 50 ohms it means
that a Z0-match to 50 ohm coax has been achieved. To understand
Z0-matches, please read my magazine article at:

http://www.w5dxp.com/energy.htm

Note: the following values are ballpark approximations.
The SWR on a dipole at the feedpoint is about 20:1. The Z0 of
a dipole is about 600 ohms. Here is the equation that governs
the 50 ohm feedpoint impedance from a 100 watt source:

(Vfor-Vref)/(Ifor+Iref) = 50 ohms

(Vfor-Vref)*(Ifor+Iref) = 100 watts

Vfor/Ifor = 600 ohms

Vref/Iref = 600 ohms

That's 4 equations and 4 unknowns. Go for it! The reflected
wave "vanishes" because of destructive interference on the
coax side at the Z0-match feedpoint.

Wonder if I could convince you that it lowers the impedance
the line sees since the voltages are 180 degrees out of
phase and the currents are in phase for a 1/2WL dipole?
The characteristic impedance of a dipole is in the
hundreds of ohms.

You might. What is the feed point impedance of a dipole that has its
ends terminated in the complex conjugate of their local impedance, so
that no energy reflects at the ends?

Hi David,

True only in free space.

>The feedpoint impedance of an antenna is usually 50 or 75 ohms.

Rarely true, but to the point of your posting, this is not
substantially wrong.

>Can an antenna ever be regarded as a transducer that transforms a radio wave
>from 50 ohms to 377 ohms i.e. provides an impedance transformation?

A transducer changes energy between domains. That is from electrical
to acoustic, or back again. Or between electrical to photo-electric,
or back again. And so on. What you are describing is transforming
and the appropriate device name would be transformer, not transducer.

To the intent of your statement, yes, an antenna is a transformer.

>With a long tapered antenna, the feedpoint is at 50 ohms. Is the end of the antenna
>at 377 ohms to launch the wave easily into free space?

The ends of an antenna are no more important than the middle.
Radiation occurs on the basis of the entire radiator, not simply
"some" parts.

>In this case, antenna
>is a travelling wave antenna e.g. broad bandwidth biconical. Does the
>impedance gradually change from 50 ohms to 377 ohms over the length of the
>antenna?

In fact it is quite the opposite. The biconical is a classic constant
impedance structure. Thin antennas such as the typical doublet or
dipole are non-linear.

>The impedance of the end of an antenna (open circuit), where it is a high
>voltage point, is usually 5K or 10K ohms.

This is a characteristic, not an explanation.

Hi Jimmie,

What was meant was that the mast inappropriately became part of the radiator due to the design of the Ringo (which has had a reputation for being a dummy load). The problem with half-wave designs is they are high Z. Being high Z they are difficult to choke. Being difficult to choke, they appropriate masts, supports, feed lines, as additional radiation surfaces. When you add these lengths to the radiator (and they are co-linear) then your radiation lobes begin to climb into the sky (no one there to hear you) and the antenna becomes deaf and dumb.

Accepting the figures as an example and not necessarily a reality...

You have just described a point which is a junction between:
- a load where the ratio of voltage to current is 50+j0;
- a feedline where:
* the ratio of the voltage to current due to the forward travelling
wave must each be in the ratio 50+j0;
* the ratio of the voltage to current due to the reflected
travelling waves must each be in the ratio 50+j0.

Having regard for the sign of the traveling waves, the only solution
to those constraints / conditions is that the reflected travelling
wave must have zero amplitude.

>
>Dipole has a standing wave on it. Ends of dipole are at high voltage. Dipole

>happens to the reflected wave? How does it vanish at centre of dipole? Why
>does reflected wave not go along feeder into transmitter output? There
>cannot be a reflected wave on feeder because SWR is 1:1.

Lets be clear that we are now talking about a single frequency.

At any point, the forward and reflected waves resolve to a single
voltage at that point, and a single current flowing at that point, and
the ratio of voltage to current is the impedance (and these are all
complex quantities, ie they have real and imaginery parts).

If the point you consider is the feedpoint, and the ratio of voltage
to current is 50+j0, then that is the impedance, it fully describes
the load at that frequency.

You talk of the "reflected wave" as if it has inertia, that it must
keep travelling when it reaches the junction of the feedline and the
antenna? You are not alone in speaking that way, but thinking that way
will get in the way of understanding what is happening. Next thing,
you will be thinking that the reflected wave must travel back to the
PA anode and will be absorbed there causing overheating.

Yeh, BUT, some coax has a smaller amount of copper
in the shield, and is therefore lossier at VHF/UHF
freqs. tho probably ok at HF. Also, look at the
RG number on the outer shieth of the coax. IF
it says " RG- 8 TYPE" instead of RG8, avoid it
like the plague , if you want to use it at VHF-UHF
, and "RG-8X" is another horse of a different
color, too, at vhf. Also, remember, that if you
are going to use for impedence transformation,
that the velocity factor of Poly center insulator
is .66 X the desired wavelength, while , Foam
dielectric, is .8 X the desired wavelength.
(No insulation, gives a velocity factor of 1.0).
In short: you get what you pay for (no free lunch)

If you write of reflected power existing on the transmission line between the tx output connector and the antenna input connector, then yes -- with sufficient tx output power and a poor enough match at the antenna feedpoint, that reflected power can cause transmission line and/or tx PA component failure.

I've analyzed and repaired many such failures of these installed systems in my pre-retirement career, and know this first hand. Conventional theory also supports this result.

Not to mention that, at VHF (and other freqs, if
you are so unfortunate, as to have cut the coax
length just right, you can show a GREAT SWR, and
still be in for problems (this like pruneing
a coax for the "Best Match")! A way to Double
Check for this, is to use a 1/4 wave (electrical)
length of coax , OF the SAME impedance, in series
with your feed line to the antenna. IF the SWR
stays the same, Should have a match, BUT IF the
SWR goes up, better check for match problems!

John Popelish wrote:
> You might. What is the feed point impedance of a dipole that has its
> ends terminated in the complex conjugate of their local impedance, so
> that no energy reflects at the ends?

It's roughly approximately the same as a terminated
Rhombic antenna, i.e. hundreds of ohms.

Let's make some rough assumptions. The SWR on the
1/2WL dipole is 20:1 which makes rho roughly
(20-1)/(20+1)= 0.9 That makes the power reflection
coefficient (rho^2) roughly equal to 0.8

If we are supplying 100 watts to the antenna then
Pfor - Pref = 100W and we know that Pref/Pfor = 0.8
So we can solve for Pfor = 500W and Pref = 400W.

If we assume the Z0 of the dipole is 600 ohms, that
makes Vfor = 548 volts and Ifor = 0.91 amps. Also
Vref = 490 volts and Iref = 0.81.

So (Vfor-Vref)/(Ifor/Iref) =
(548-490)/(0.91+0.81) = 58V/1.72A = 34 ohms.

But that is just half of the dipole's impedance so we
have to double it to get a feedpoint impedance in the
ballpark of 68 ohms. However, please note that 34
ohms is roughly the feedpoint impedance of a 1/4
wavelength monopole, i.e. half a dipole.

These are obviously rough ballpark assumptions but
you can observe the concepts involved. For the dipole
feedpoint impedance to be low, the voltages have to
subtract and the currents have to add. This agrees
with the extra 180 degree phase shift that happens
when the current is reflected at the ends of the dipole.

The mechanism is not "that the reflected wave must travel back to the
PA anode and will be absorbed there causing overheating".

Take an example of the 50 ohms load discussed, and an electrical half
wave of 70 ohm line connected to a transmitter designed for a 50 ohm
load. The transmitter behaves exactly as if that line were 50 ohms.
Though there is a reflected travelling wave on the line, it does not
travel back to the PA anode where it is absorbed and converted to
heat. At the tx end of the line, the forward and reflected wave
components resolve to a 50+j0 load, and the transmitter sees the same
50 ohm load as it would were 50 ohm line used. Increasing power or
increasing line Zo for a higher VSWR will not change the outcome of
this example.

Sorry Owen, that's not true. Assuming a 1/2WL dipole,
the reflected voltage has traveled 180 degrees. The
reflected current has traveled the same 180 degrees
plus experienced a 180 degree phase shift at the tip
of the dipole. Assuming 100 watts is being applied to
the antenna, the following conditions satisfy the
observed conditions on the dipole at the feedpoint.

Pfor = 500W, Vfor = 548V, Ifor = 0.91A

Pref = 400W, Vref = 490V, Iref = 0.81A

Pnet = 100W, Vnet = 58V, Inet = 1.72A

It is well known that all EM waves contain energy and
momentum (inertia) so David is correct. The thing that
reverses the momentum of the reflected wave is destructive
interference at the Z0-match point. Anyone interested in
understanding how/why it happens is invited to peruse
my energy analysis article at: http://www.w5dxp.com/energy.htm

Of course not. Destructive interference redirects the energy
back toward the load at the impedance discontinuity. The same
thing happens with a 1/4WL thin-film on non-reflective glass.

Jim, can you explain what is going on here, why what happens happens.

It has more to do with what is happening on the outside of the coax
than on the inside of the coax.

Cecil, the statement was in the context of the previous paragraph. The
travelling waves I was referring to where the ones I had just
discussed which were on the transmission line (and NOT the dipole).

Owen

I apologize. I thought you were talking about the antenna.
I just reread it and it's not clear to me what was being
discussed.

You got cut & paste down pretty good Mark. Now if you could only get
amateur radio down, you could be a real ham and not a dumbed down one.

Ping real Hams,

You'll want to use CW if you ever have to save len Anderson, that
should help him change his brain cell regarding the value of Morse.

Thanks

Quite easily. Impedence matches repeat, every 1/2
wavelength. This is the basis for those old "CB"
shops , pruning the coax for the best match
(rather then the antenna)! At ODD multiples of a
1/4 wavelength. the coax, becomes a MATCHING
Transformer (like stacking 2- 50 ohm antennas,
you use 1/4 wavelength sections of 75 ohm coax)
In this case, we are matching 2 -50 ohm loads to
a 25 ohm source)-- Coax has a characteristic
impedence that is constant along its length.
as long as the Source Impedence = the Load
Impedence. IF the source is DIFFERENT from the
load impedence, or the Coax has a different
impedence, from the source and/or load, however
the source/coax/and load will show 1:1 SWR,
AT the 1/2 wave points of the line, repeating
EVERY 1/2 wavelength! However, as stated, ODD
1/4 wavelengths become a impedence XFMR.
(the formula being : X Zo (1/4 wave) = the
SQUARE ROOT of R1 x R2! Was well documented in
an a old VHF'er article from the '60's!
Ill post it (in text format, when I find it-- Jim

I don't know of a one who believes that.

The earth has been warming and cooling for a very long time. Pretty much fact also. Some who believe that the earth was created in 4004 b.c.e might contest that.

The question of whether the so-called greenhouse gases have an effect on the retention of heat in the atmosphere is just about as plain a fact as there is. There are laboratory experiments, and comparisons with other planets in our solar system.

Without "greenhouse gases" we simply wouldn't exist.

But the question is whether the amounts that we have introduced into the atmosphere will have any effect.Here is a link that lists known greenhouse gases:

http://en.wikipedia.org/wiki/IPCC_list_of_greenhouse_gases

Okay. Does our increase of 87 ppm from 1750 c.e. or the 1045 ppb increase in methane during the same time period have any effect? Or do human based sources have no effect, only natural sources

Interestingly, if as Cecil alleges, when we hit ~280 ppmv, we trigger an ice age. Well, we passed that level some time ago. in 1998 we were at 365 ppmv.

> Just wait until the next ice age, even a minor ice age, then they, the
> GW advocates, will be demanding more CO2 in the atmosphere. :-)

Considering that another ice age will mean the loss of a good part of
humanity, that idea might have some merit.

If the SWR on a line is 1:1 at any point, it is 1:1 at ALL points on
the line.

If the SWR on a low loss line is close to 1:1 at any point, it is
approximately the same at ALL points on the line.

On practical lines at HF and above with practical loads, the SWR
decreases smoothly from the load to the source because of line loss,
the lower the loss, the lower the rate at which SWR falls as you
approach the source.

If lengthening the line increases the SWR at the tx, or decreases it
by more than accounted for by the extra line loss, then something else
is happening.

Be careful regarding 1750 bce.

That predates the industrial revolution by at least 100 years. This indicates that natural factors are at work.

Petroleum products date from the 1880s. This indicates that natural factors are at work.

Automobiles date from the early 1910s. This indicates that natural factors are at work.

Deforestation dates from the mid 1950s. This indicates that natural factors are at work.

The period of 1700 to 1750 is acknowledged as the end of the 'Little Ice Age', not the beginning of manmade [man contributed] GW.

There are so many unknown contributors to the earth warming and cooling cycles that blaming CO2 and other 'greenhouse gases' for the major cause is just irresponsible.

IMO, GW = K1*d(solar activity)/dt + K2*d(volcanic activity)/dt + K3*d(El Nino)/dt + K4*d(La Nina)/dt + K5*d(deforestation)/dt + K6*d(radio carbon decay)/dt + K7*d(many other factors)/dt + Kn*d(n)/dt ...

What is known is that the earth warms and cools. Why? That is still open to discovery.

/s/ DD

PS: Most Christian Clergy of major denominations agree that the cosmos was formed between 15 and 20 billion years ago. The 4004 bce calculation is incorrect and is the result of poor biblical scholarship.

3753. FS: HP/AGILENT 432A PowerMeter (RF/Microwave), SENSOR INCLUDED, 10MHz - 40GHz or up dep. on sesnor. WORKING PERFECT

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-05 00:43:15 UTC
From: Marco Licetti <StanisDEATH2SPAMMERS@DEATH2SPAMMERSprodigy.net>
Message-ID: <DK3Lg.6321$yO7.997@newssvr14.news.prodigy.com>
Source record: 53140

HP/AGILENT 432A PowerMeter (RF/Microwave), SENSOR INCLUDED, 10MHz - 40GHz or up dep. on sesnor. WORKING PERFECT
Warranty.

Should goto 40GHz according to Agilent website, but maybe HIGHER depending on sensor. Fact we never used it above 26.5GHz at the time it was put to storage, only recently we started testing amplifiers above 26GHz, our new meter is at least 110GHz. Just check with Agilent website.

Do NOT reply on Newsgroup, if email: remove "death2spammers" strings in my address (repeated twice). Price $69 with sensor, mere sensor CABLE alone could be $100+ and I am giving it to all for 70 dollars: powermeter itself, sensor, cable. Have NO time to wait for auction to end, we just need to sell and be done. I by the way moving on Sept30 myself, and need to unload some weights. PLEASE do check with Ebay listing first as I might revise it. Shipping from Amplitech, Inc., New York, USA

Posted on Ebay, item# 330025215168. Goto www.ebay.com and enter "330025215168" (without quotation marks) into search window (or item#, etc.); BUY NOW OPTION is AVAILABLE, i.e. NO need to wait for Auction end ($799 or revised down). Description is there (on Ebay), copied down here for your convenience, BUT to see ALL-SIDES PICTURES/etc do check that Ebay listing. Best done via Ebay - SAFE for you/me (my feedback is 100% positive there & 10+ years on Newsgroups), if you're not into Ebay and unless a bid already placed, I can take it off and sell outside Ebay. Description copied here (see pictures on Ebay):

*****
Concise description as you can GET DETAILED DESCRIPTION/SPECS/MANUAL at AGILENT website (www.agilent.com->search->enter 432A, power). People who buy Test Equipment are professionals/engineers - know already the specific model specs or can quickly locate. HP/Agilent 432A is Analog but widely used/known legacy RF/microwave powermeter.

1. WORKING PERFECT - warranty, was CALIBRATED several years ago but now expired so you MAY want to recalibrate.
2. INCLUDES SENSOR & CABLE: 486A, THERMISTOR MOUNT - 200 Ohm (?), WAVEGUIDE TYPE + CABLE i.e. COMPLETE SYSTEM READY FOR USE.

PULLED FROM WORKING ENVIRONMENT at AMPLITECH, Inc. (www.amplitechinc.com), one of the best-known RF/Microwave companies - a spin off of Miteq, Inc. Used to test military amplifiers originally, then as a backup, and finally put to storage sas we upgraded to EPMseries Agilent powermeters.

Docs/specs/manuals are at Agilent website, a simple meter comparing to dual-head/modern meters. If you see only info on meter itself and not sensor, the calibration factor/effective efficiency are printed on sensor body, NIST-traceable. Looks like a metal barrel waveguide port - I could add pictures but for such a cheap item I can only post one picture - meter itself (any extras would cost me money). Agilent website mentions: "automatic, self-balancing power meter for use with temperature compensated thermistor sensors" and something "10MHz - 40Ghz" (can be expanded with different sensor?).

Reason to sell:
We were fortunate to afford a company-wide upgrade program, e.g. in place of this, 436A and 437B powermeters we're now using dual-head $4000 Agilent EPM units, so 432A is up for sale. I sold 436A earlier - see my feedback list.

Can be used as a backup for your Tech if you can only afford modern meters for your engineers, or as a primary meter for Ham/etc. Radio amateurs, space radioastronomy, or any application you may want a cheap WORKING Microwave meter for that can go to multioctave Gigahertz region. Could keep to myself but we now have excess powermeters and instead need money for Network Analyzer parts (i am also interested in HP 8350B plugins for 20GHz at least, 26.5GHz better)

> is just irresponsible.

No it isn't - or at least look at your statement for a second.

Greenhouse gases are not responsible for the majority of atmospheric heat retention. Water vapor is. And there isn't a lot we can do about that.

You are redefining my argument. I am saying CO2 and other gases such as methane, which do indeed represent a portion of the heat retention, are present as a greater percentage that they were in the past.

I'm also saying that the additions are such that an increase in the atmosphere's heat retention capacity should be seen. Nothing odd about that. It can be shown experimentally.

Then the main thing I am saying is that if it isn't, then WHY isn't it? If we just say "we don't know", and can offer nothing except calling people who think that global warming might exist, and offer evidence, and our own evidence consists of insults and rhetoric - well that is what I consider irresponsible.

Lots of reasons. Precession, Solar output, volcanic action, maybe a
stray asteroid or two. CO2 Methane, albedo.

Most scientists say it was ~12.5 billion years ago.
That assumes constant length seconds which is an
illogical assumption. If the length of a second
has changed drastically, 7000 years may be correct.

If the length of a second has changed drastically, 7000 years may be
correct.
Possibly the most absurd thing I've read so far. A most disengenuous
argument.

Are we now going to abuse the theory of relativity to satisfy the
convenient lie of creationism?

Have we moved from Darwin to Einstein?

Are Copernicus and Galileo next?

How about Roger Bacon? (who?)

Oh, wait, it's Cecil. I'm fished-in again.

Owen
Keep in mind that I'am (primarily) VHF/UHF op.
You might find this interesting (- the drawings)!
This from the VHF'er, Nov, 1964-- Jim
ACID TEST FOR A FLAT TRANSMISSION LINE Loren Parks
K7AAD (BTW, Loren runs Parks Electronics, in
Portland, Or. and has given up ham radio long ago!)

The mark of a beginner is blind faith in meters.
Most hams get over believing an "S" meter after a
few years, but very few get to the point of
doubting that SWR or power meter. You ought to try
hooking half a dozen SWR bridges and power meters
in series with your transmission line--all at the
same time. If the line is not properly terminated
you'll probably get as many different readings as
you have meters.
An SWR bridge or wattmeter can show zero reflected
"power" or nearly so on a badly mis-matched
transmission line. This is why the beginners
"prune" the transmission line to " get the SWR
down." Pruning can help you load into a badly
mismatched line but the seat of the trouble is in
the termination--the antenna.
The proof of a properly terminated transmission
line is that changing its length has no effect on
transmitter loading or on an indicator in the line
ahead of the length that is changed. If your
bridge now shows little or no reflected power or
voltage, it may be that it is inserted at a null.
Therefore you have to move the null, if any, by
changing the distance from the meter to the load
(not the transmitter.) Inserting 1/4 wavelength
(electrically) of coax will give a maximum change
in meter reading.
Insert lengths as shown in the table below. Make
some allowance for the additional length of
fittings or adapters at 432 Mc. Dimensions are not
very critical.
Added length of Original length of
transmission line transmission line
Transmitter
SWR Bridge or Power Meter
Changing the length of the line to the right of

the bridge or power meter should have no effect on the meter reading, regardless of the quality of the bridge or power meter. Plate current in the transmitter should not be affected either. If changing line length affects any meter reading, the transmission line is not properly terminated which means the load is not matched to the line. The degree of mismatch will be indicated in a relative manner by the amount of change in meter readings.

M
Antenna
236" x .66 = 39" 4
144 Mc. 82" x .66 = 13.5" 4
220 Mc. 54" x .66 = 8.8" 4
432 Mc. 27.4" x .66 = 4.5" 4
50 Mc.
It is possible that you will get a reflected energy reading that is approximately the same when you insert the quarter wave length line. This is because you are shifting phase 90 degrees and perhaps just moving to the other side of the "hump" in the line. Try different lengths of line, shorter or longer. Put most faith in whatever readings make your line look the worst. You cannot believe SWR values obtained from transmission line type instruments (monimatch) in which the line is an appreciable fraction of a wavelength. At 6 & 2 this is not a problem, but at 432 it is.
knurled
lock-nut -p
A commercial "line stretcher." This one telescopes 20 cm. while maintaining a constant characteristic impedance of 50 ohms. It is most useful at 432 Mc. and above where 1/4 wavelength is about 17 cm. in air.

SWR bridges and power meters are very valuable instruments, properly used. End.

Also, found a article by the same, useing a 400 foot run of RG-58 U for a dummy load, terminated with couple 2 Watt 100 ohm resistors (truth be known, at 6 meters, and up you dont even need the resistors! The effect, tho is the same, on ANY freq, as long as the 1/4 (or the 1/2) wavelengths apply! Jim NN7K

Several large regional deforestations have taken place over Man's history. Recall that Lebanon's flag is a cyprus tree...now nearly desert, Lebanon serves as dramatic evidence of deforestation during the Bronze and Iron ages. Deforestations occurred in Mayan lands around the time of Christ.

The chief difference today is that deforestation occurs all around the globe more-or-less at once.
>

Hogwash. The grand majority of scientists working on these issues do not refute manmade impacts on GW (excepting, of course, those receiving paychecks from industries primarily responsible for them.) Unknown factors will always exist, but scientific consensus has been already been achieved on GW.
>
> IMO, GW = K1*d(solar activity)/dt + K2*d(volcanic activity)/dt + K3*d(El

The argument for GW is no longer in dispute within the scientific
community. Cyclicity of global temperature does not negate the argument
that the current run of GW is something new and unprecedented. Right
now, governments are already planning for projected effects.

It's here, it's now, it's WOW.

Ask any Baptist and you'll get the 4004 answer...the "one-second-used-to
be-a-million-years" argument notwithstanding.

Again,
My understanding of the notion of GW is that human activity is now
PERTURBING the cyclicity that already exists. Pre-existing cyclicity of
global temperature cannot in itself refute the argument for the
existence of GW as a "new" phenomenon. They're intertwined.

Not at all. We know the length of seconds change with
velocity. We could easily calculate an initial velocity
and a present velocity that would make the universe
7000 absolute years old. (absolute as opposed to relative)

> Are we now going to abuse the theory of relativity to satisfy the

When one thinks of high technology today, those products involving microchips and computers tend to come most quickly to mind. But, according to Elias Romo, developing a more efficient transformer or producing an entirely new breaker design are equally valid and perhaps more enduring examples of high technology at work. Says Romo, "developing such equipment is certainly not easy. You need prototypes, testing laboratories and, of course, highly-qualified people."

It was more like 4000 something according to people I am acquanted with
that believe in those fairy tales.

And I won't vote for either of your parties. Both are just as corrupt.
Like you Richard, who vote for a yellow-dog-democrats, I will vote for
anything that has breath that is Libertarian.

You got me. Yes, I think it IS a Cedar tree, not a cyprus.

Incidentally, I recall that the island of Cyprus is named for the element copper, heavily mined on the island and smelted (with the help of the CEDAR trees for the furnace).

When I'm at home I get a weak cellphone signal. Walk outside and the signal becomes strong.

Is it possible to connect two external cellphone antenna together and put one in the attic, the other inside my house to improve the situation?

3766. G5RV trimmed for voice?

Source record: 53153

I was looking through the G5RV instructions including the original article, and it's clear the antenna, when it is 102 feet long, is tuned for the bottom of the bands. Anyone have any experience trimming one down to resonate in the mid part of the voice bands?

>you'll probably get as many different readings as
>you have meters.

The author is not stating what has happened, what he has observed, but an opinion on what he thinks may happen.

Assuming that he is talking about the common reflectometer / directional wattmeter instruments that sample current and voltage in a very small region to determine SWR, that they are suited to the frequency and line, and they are of quality...

The fact remains that on practical lines at HF and above with practical loads, the SWR decreases smoothly from the load to the source because of line loss, the lower the loss, the lower the rate at which SWR falls as you approach the source.

Any difference between instruments for direct or indirect measurement of VSWR placed in a uniform practical line is accounted for by line loss and instrument error (eg its indication or disruption of the line). The line loss between adjacent meters in practical coaxial lines (which is where you are likely to be using an SWR meter) on practical loads is very low, and so quality instruments should read almost identically.

To take an extreme example, using RG213 at 1296MHz, and two SWR meters spaced 0.3m (~1') apart, if the SWR on the line at the one nearest the

source is 3:1, the SWR on the line 0.3m closer to the load is 3.1...
you would probably not see the difference. If on actual test, two
meters showed significant difference, there is instrument error in at
least one of the instruments.

... lots of confused stuff clipped

>
>SWR bridges and power meters are very valuable
>instruments, properly used. End.

Prophetic!

> with couple 2 Watt 100 ohm resistors (truth be
>known, at 6 meters, and up you dont even need the

Yes, the input SWR of a 400' o/c stub of RG58 is about 1.1 at 50MHz,
and gets lower with increasing frequency.

>resistors! The effect, tho is the same, on ANY
>freq, as long as the 1/4 (or the 1/2) wavelengths
>apply! Jim NN7K

I don't really understand how the 1/4, 1/2 relate to the dummy load?

I am interested in the origins and purpose of the "IRE (Institute of Radio Engineers) Standard Dummy Antenna," as used during the alignment of radio receivers.

I first came across this circuit in some old Hallicrafter's documentation, which described the alignment of a particular radio. The "IRE Standard Dummy Antenna" consists of four components--- a 200pf cap in series with a 20 uH inductor, which links the signal generator to the receiver's antenna input. A 400 pF cap in series with a 400 ohm resistor is connected in parallel with (shunts)the inductor.

I gather that this circuit models a wire antenna of some type. Is this true? What is the import of the component values and how were they arrived at? I modeled the circuit in Spice and graphed the transfer and impedance curves but it is not entirely clear to me what benefit there is to using this circuit.

I've also Googled this and found some references here and there, but nothing explains the "why" of it.

Is there anyone who can shed light on this?

Or more specifically, it's to present a uniform high impedance
from the generator to the radio. At the time, with the exception
of a few lab grade instruments, signal generator outputs were all
over the map with regards to output impedance. The "dummy antenna"
presented a fairly uniform, and high, impedance to the radio and
kept from detuning the front end while doing an alignment while
connected to a signal generator.

Hi Owen,

The same thing will happen if you put a SWR (or Power) meter between
the two mismatched ends of a transmission line. In this case it is
not instrument error, it is systematic (application of the instrument)
error.

There is no standing wave on the antenna. The distribution patterns of
voltage and current on a half-wave dipole shown in antenna books, is not
a standing wave. They are the RMS values of voltage and current along
the dipole. At the centre, the ratio of Vrms to Irms is 50 ohms.

Ahhh, so for the very first time, I finally hear an answer to one of those things that I've scratched my head about for years!

I've often wondered why the literature always says to stick a capacitor inline from the signal generator -- I figured if I had to do this all the time, then why didn't the signal generator maker put one in there? Turns out, usually they do, but it's probably not an impedance match. Still, for most radios I just stick the probe to the antenna and go to town. It's fine for the IF -- enough of it gets past the RF to give me a workable signal. Then for RF I use whatever frequency I need to check/adjust the LO. For final RF adjustments I plug in the antenna and tweak it up on a weak station.

Again, I probably differ from most of you because I work mainly with car radios. I already have a pretty decent antenna at the bench -- some $10 special from Auto Zone -- that does a great job. On a conversion there are no RF adjustments; on a repair/rebuild, I can do every adjustment except one, the one which must be done inside the car anyway -- the antenna trimmer. However even this gets checked -- I've noticed that with my bench antenna, the trimmer usually adjusts toward the "high" end, with the screw fairly loose. So if the trimmer tweaks in this area I'm fine. If it tweaks "tight", or not at all, I'll adjust the slug as needed -- or troubleshoot.

Actually it is rare that I ever have such a problem -- with one exception: the 58-60 T-Bird radios. Even these are just fine, usually, but I've had a number of them whose front ends are way off. I've spent many hours trying to figure out why, and come up with nothing. I've replaced RF caps, checked the range of trimmers, checked resistor tolerances, and basically gone over the circuit with a fine tooth comb. Everything checks perfect, but the alignment is out. So I adjust the tuning slug -- a pretty fair distance --

to bring it in line. I've had a couple that were so far off that I had to tinker with the others as well. It's really fun because those slugs are WAA-AAY up in there, and difficult to reach. You can't do it with a non-ferocious screwdriver, or even a ferocious one -- it's too tight. You have to reach the shaft with needle-nose. In any case, all this fun aside, I can tinker and bring it into line -- but I still wonder why I have to do it in the first place.

I think my next step in this "investigation" is to spend time with the next 58-60 T-Bird I get for conversion. If it's a good radio, when I disassemble I'll measure the tuning slugs, trimmers, fixed coils, etc., and write them down for reference.

Hello, and I would like to point out (from experience at work) that Pasternack is a convenience store for bulk RF connectors and pre-made, connectorized RF cables - You will save time but you will pay big $$ (e.g. compared to Rat Shack or a Ham fest for a similar item) for it. They are prompt, however. Sincerely, and 73s from N4GGO,

Really, the mechanism is there -- only the unique circumstance you describe protects the PA from seeing reflected power in such cases. Other line lengths in this scenario could stress PA components beyond their ratings.

And even if the PA saw no reflected power because of a fortunate length of transmission line connecting it to a mismatched antenna/load, that reflected power still exists in the transmission line, and may cause its failure.

Manufacturers of the rigid coaxial line used in broadcast stations (e.g., Dielectric) require derating its maximum power rating inversely by the value of the SWR existing in it . A power derating factor related to SWR also applies to Andrew Heliaxï¿½ and RG-type coax line. Deliberately setting up, or tolerating reflected power on a transmission line is not done without risk.

Actually the document you are referring to is just one way to
establish the earliest date of invention, which is all that the patent
office is interested in. In other words, if someone can prove that
they made the invention prior to the filing of your written document,
then the earlier inventor gets priority.

The patent office determines who is the first inventor by means of an
"interference proceeding". The written document you refer to would be
just one piece of evidence at such a proceeding, but could readily be
overcome by any other convincing evidence of an even earlier date of
invention by someone else.

You can read all about this topic on the patent office web page:

http://www.uspto.gov

From "Antennas" by Kraus & Marhefka: "A sinusoidal current
distribution may be regarded as the standing wave produced
by two uniform traveling waves of equal amplitude moving in
opposite directions along the antenna."

From "Antenna Theory" by Balanis: "Because of the standing
wave pattern, it is also classified as a standing wave antenna"
"The sinusoidal current distribution of long open-ended linear
antennas is a standing wave constructed by two waves of equal
amplitude and 180 deg phase difference at the open-end traveling
in opposite directions along its length."

Of course, a 1/2WL dipole is a standing wave antenna.

------------ REPLY FOLLOWS ------------

No, this is not that type of circuit. This uses a simple vertical whip without any loading coil. At the base of the whip there is a variable coil and variable capacitor in parallel with each other and connected to ground. From the junction of the whip and coil/cap there is another capacitor which goes to the input of a 4:1 unun which steps up the resultant 12.5 ohm impedance to 50 ohms, which goes to the transceiver.

For 3.5 MHz, the values in his example are 44 uH for the coil and 11.9 pH for the cap which feeds the unun. The value of the variable cap in parallel with the coil is not specified. He states that exact values of all components are highly dependent on coil Q.

I see two major advantages to this network:

1. The whip itself is as simple as it can be; no loading coil at all.

2. The value of the coil at the base is smaller that a conventional loading coil would be.

One drawback, although the author does not state it, is both capacitors must see a LOT of voltage, and vacuum variables would probably be necessary. At the 100 watt level, I'd guess the voltage there is on the order of 2-4 kV, possible more.

If anyone is interested, email me at my qrz.com address and I'll send a screenshot of the circuit and the text of the article.

If you will download the free demo version of EZNEC from
www.eznec.com, I will send you the .EZ model of a g5rv
and you can experiment to your heart's content.

The problem is if you shorten the series section to make
the G5RV resonant on 3.8 MHz, it will tend to resonate
on 40m at 2 x 3.8 = 7.6 MHz and on 20m at 4 x 3.8 = 15.2
MHz. You can always improve one band at the expense of
others.

You can improve 75m performance by installing a 1000 pf
silver mica cap across the twinlead at the twinlead/coax
junction but that cap needs to be removed for the other
bands. When I ran a G5RV, I used a clip on capacitor.
If you like 75m, try the cap.

Hi Peter

A passive repeater?

Yes they work but it may not solve your problem. It's the kind of thing
that may need some modelling etc first.

I use to have one setup where the outside signal was "very strong" but
the inside was "very weak". That worked well. I also (commercially)
modelled for a tender a railway cutting/tunnel (improvment) that was
about 3km from the base station. That bought the signal level in the
cutting from about -107 to -85dBm.

You may find a signal improvement only occurs with a few metres of the
inside antenna. Like I said it needs some modelling.

You will probably need a gain antenna (eg yagi) outside the house and
not in the attic.

There are also active repeaters azvailable for cellphone bands. They may
or may not be legal for use in your country though.

Cheers Bob VK2YQA

Yes, the exposure of the PA to reflected power depends
upon the phase of the reflected wave referenced to the
phase of the source wave. SWR doesn't tell the whole
story because phase is not reported by the SWR
measurement.

What is happening with 1/2WL of Z0=600 ohm feedline
connected to a 50 ohm load on one end and a 50 ohm
source on the other end is interference. Destructive
interference toward the source causes constructive
interference toward the load and the reflected energy
at the source is re-directed back toward the load.

What we want to avoid in our antenna systems is
constructive interference toward the source.

What is a Libertarian?

Libertarians believe that you have the right to live your life as you wish, without the government interfering -- as long as you donï¿½t violate the rights of others. Politically, this means Libertarians favor rolling back the size and cost of government, and eliminating laws that stifle the economy and control peopleï¿½s personal choices.

I'll send for the schematic but it sounds like he has
a resonant circuit at the base. If so, he has increased
the current through the coil considerably and losses
in the coil are proportional to I^2. Reducing the size
of the coil doesn't help if you increase the current
through it. Sounds like he is forcing self-resonance
in the coil by adding external capacitance. That
cannot be a good thing for efficiency. I'd like to
see his design up against a good screwdriver at a
75m mobile shootout.

Consider that moving a center-loaded coil to the base
of the antenna allows the coil to be made smaller but
the overall losses in the system increase considerably.

I believe you are correct. This would be an expensive system to
implement and perhaps not as efficient as a traditional system. It
would be interesting to do a shootout.

As he states, one of the main advantages is having a whip with no
loading coils, even on 75 meters.

Whether the source sees that reflected power or not, that reflected power is stressing the transmission line -- regardless of the electrical length of that line at the operating frequency.

IOW, for these unique conditions the source may be unaffected by the reflected power in the line, but the line itself is still stressed by that power -- and possibly to the point of failure.

Look online for a free or cheap old parabolic dish. Stand it against
the wall inside and sit in front of it while using your cellphone. If
you are able to point it to a tower and find the sweet spot, you can
find some gain there.

The "sky is falling folks" also fail to take into account the nutation of the earth that causes the earth to be tilted towards the sun a bit more... Kinda like the difference between winter and summer tilt.

It takes one hell of an ego to think that puny man can affect the earths climate. Notice those that are the loudest voices live packed atop one an other, smelling bus fumes in big cities. They think the rest of the world is exactly like there limited universe.

I still await an explanation of how freon, that is heavier than air, manages to make it to the South pole and finds the magical propert to climb to the ionisphere and eat ozone.

But as always, there is no money in truth, nor can it stop the evil industrial military complex...

In the late 1800's, most of Central PA was deforested. Either for
lumber, or for the iron industry. I was told that you could go to the
top of Tussey mountain south of my QTH, and not see a single tree in any
direction. Since the people who were making the charcoal that was used
to make the iron thought that planting new trees wasn't a cost effective
option - if they indeed thought about it at all - they eventually ran
out of fuel.

We still are enjoying the effects. What has grown in the original
lumbers place is nowhere near the quality that existed before. We mostly
grow pulpwood now.

Humans really *do* have an effect on the environment.

Body handling: HTML body converted to readable text

The G5RV requires a tuner, this obviates trimming the antenna for any
portion of a band.

If you look at the total antenna system (feed line length and antenna
length) you will find that shorting the antenna and leaving the feedline
length alone will result in not being able to tune the high end of the band
on 75 meters using most commercially available tuners.

If you plot all frequencies betwee 3.5 and 30 Mc you will note a large hole
just above 4 Mc where no practical tuner can create a match.

Yes, the dummy antenna models a wire resonant at 2.something Mc. I suppose that was taken to be more or less typical of the receiver antennas of the 30s. The dummy antenna's most important use is as a standardized load for measuring receiver sensitivity. Terman's Radio Engineer's Handbook has a few paragraphs on this.

If you're just adjusting the RF coils, peaking them up on the antenna normally used would be as good or better. Any sort of loose coupling between the generator and RF coils will get you in the ballpark with most radios.

This doesn't sound right, why would it be desirable "to present a uniform high impedance from the generator to the radio"? The impedance of the "IRE Standard Dummy Antenna" is not exactly what I would call "high" especially on some of the short wave bands, exactly what is a high impedance in this context?

It was my understanding that the purpose of the "IRE Standard Dummy Antenna" was to provide a standard antenna to use for making performance measurements, as well as for alignment at the factory and on the service bench.

As to the exact design of the of the "IRE Standard Dummy Antenna", I understood that it was meant to represent the impedance characteristics a typical antenna that might be used by a radio set owner. This topic has been discussed here before and I seem to vaguely remember that someone may have even dug up the exact nature of the antenna the "IRE Standard Dummy Antenna" was designed to simulate. IIRC if you are only doing MW broadcast band alignments a single capacitor will provide a very good approximation of the "IRE Standard Dummy Antenna" across the MW broadcast band. The coil, resistor and second capacitor are there mainly to provide the desired impedance on the short wave bands where the prototype antenna has resonant effects

There are at least two problems that the "IRE Standard Dummy Antenna" solves, the first being standardized measurements for obtaining

performance specifications, as it is possible for a manufacturer to "improve" his products specifications by using his own specially designed "Dummy Antenna". The second problem is how to align sets in the factory, or on the service bench, when the final users actual antenna system is not available. The problem is that the alignment of the antenna stage of a radio is greatly affected by the impedance of the actual antenna that is used with the radio. The "IRE Standard Dummy Antenna" provides an approximation of what was assumed to be a typical consumer antenna. Of course what you really want to do is align the set with the actual antenna attached that it is used with.

No not crazy.. You would certainly get gain but the question you have to ask is whether it is enough to overcome through wall etc losses. You also have to keep in mind that the signal you are using might be via reflection rather than direct. ie the direction you point may also need to be played with.

It would be a great talking point for the occasional visitors too!

Cheers Bob

Hi Tom,

I've probably voted for more Libertarians on one ballot than either of them in their lives. We need more genetic diversity in the political gene pool. Problem is those parties don't work nearly hard enough to build a grass-roots. Umm, I should ammend that and say they don't work at all to do it.

Third parties are invariably so self-centered that they want to start at the top (notably Lyndon Larouche). Unfortunately, courtesy of W we now have an example of how that turns out when the most left wing fascist elements put their man in at the top, and the right wing has voted in politburo lock-step to advanced the party planks of Leon Trotsky. All Larouche needs to learn is how to haul down the flag, and start waving bacon.

I don't see any information at that web site about the type of vehicle. Since the vehicle radiates an amount comparable to the antenna, it can have a profound effect on the overall field strength. Were all those antennas mounted on the same type of vehicle?

Hi Fred,

Hmmm, water is heavier than air. How does it manage? Even clouds are
heavier than air. Rain comes from asteroids, comets, and meteors?
Dust is heavier than air, as is smoke that comes from China and lands
here in Seattle.

They all rise from the same mechanism - sunlight. Heat generates
convection currents. Currents raise pollution that traps heat. More
heat generates more convection currents. More currents raise more
pollution.

Arguably "more" is by slight degrees, but as any capitalist knows,
compound interest is where the money (pollution) is, and most
technicians have had experience with Thermal Runaway.

It's probably more critical on VHF/UHF, but on the HF bands I never
had any trouble with ringos and decoupling problems overly skewing
the pattern. I've used a few with no decoupling at all, and they
worked
fine. But I'm of the opinion that the "gamma loop" type feed helps
decouple the feedline a bit better than some other methods of feeding.
I tried adding a decoupling section to one I used on 10m a few years
ago, and it did help, but not in a huge amount. I found the antennas
pretty easy to choke by using a 1/4 WL section of coax, and then 4
radials.
Much the same as used on the "ringo ranger" antennas. Anyway, I've
never seen a case on HF where I thought a ringo acted like a dummy
load.
I imagine it's possible on VHF though, if precautions aren't taken.
I've used lots of them on 10m at various heights. Always worked pretty
well. And I never noticed an overly hot feedline.
The only times I had horrible results with a half wave was a time years
ago when
I tried to make a center fed job, using peeled back coax braid as part
of the
antenna. The decoupling from the line was horrible on that thing.
That was on VHF though where the problem shows up more.

I imagine it's possible on VHF though, if precautions aren't taken.
I've used lots of them on 10m at various heights. Always worked pretty
well. And I never noticed an overly hot feedline.
The only times I had horrible results with a half wave was a time years
ago when
I tried to make a center fed job, using peeled back coax braid as part
of the
antenna. The decoupling from the line was horrible on that thing.
That was on VHF though where the problem shows up more.
MK

>
> The author is not stating what has happened, what he has observed, but
> an opinion on what he thinks may happen.

What happens is IN a HIGH SWR Mis-match, is that
the SWR (true) can only be measured at the load
end. The reflected wave (Say infinity:1 is NOT a
constant, over the entire length of your coax, but
will take on the sinusoidial of the wavelength
for voltage (or current). Obviously, the reflected
wave repeats the voltage, every 1/2 wavelength
(- coax loss's), going from a 1:1 match, to a
infinity to 1 mis-match, every 1/4 wave length
and, then back to a 1:1 match,the next 1/4 wave.
If you were to graph this out for 1 cycle, you
would see a start at 0 volts, raiseing to maximum
volts, then dropping to 0 volts, and then to
Maximum Negative volts.This repeats all the way
from the source to the load! A perfectly
matched coax, on the other hand will have the same
voltage measured , no matter the length of the
line (again ignoreing the line loss's). (straight
line graph, not a sin wave).

> which SWR falls as you approach the source.

This is academic, as the True VSWR still exists at
the load. If it is 3:1, at the load, but you
measure 1.5/1 at your rig, the difference is
because of line loss, NOT that the 3:1 swr has
been corrected! Worse, (usually on short coax
runs with a bum load, is the effect, that you
have MORE POWER reflected, than was applied to
the coax (an impossible situation)!
>
> Any difference between instruments for direct or indirect measurement

> you would probably not see the difference. If on actual test, two
> meters showed significant difference, there is instrument error in at
> least one of the instruments.

Keep in mind, that WHEN a swr exists, the sin wave
effect also exists irregardless of the freq you
are on. and also, IF you measure at a null point
where the forward power wave voltage cancells the
reflected voltage (for 0 volts), the introduction
of a 1/4 wave length (electrical), will force your
meter to the voltage MAXIMUM ! 'corse, the best
place to measure a mismatch is at the load,but
try it sometime! Try about 13-1/2 inch long
piece of coax, on 2 meters added to your
mismatched load, and then remeasure the swr-
you will see what Im talking about!

> and gets lower with increasing frequency.
>

Only to say this why your swr APPEARS lower (coax
loss)
but that doesnt effect the REAL swr of the load!
With the 400 foot of coax, the losses are so high,
you wont even see any reflected at the source end-
but at the load end, you will have infinity :1 SWR!

Those are averages, Roy, not associated with any particular
vehicle. The average screwdriver beats the average hamstick
on 75m. Using similar antennas, the larger vehicles (GMC
pickups) usually beat the smaller vehicles (Honda Civics).

Doldrums, like the depression currently encountered by voters with the
current administration? Or Doldrums as in the Horse Latitudes, trade
winds and all that lower atmosphere stuff that resides below the Ozone
layer that Freon (CFCs) has been eroding?

Let's see, you put together CFCs, Ozone, and ionizing radiation where
it is (and not where it ain't) and you punch a hole from the
combination.

I suppose if the earth's magnetic poles were situated in Morocco and
Hawaii (the east and west pole?); then the stream of ionization
radiation from the sun, combining with the far richer CFC and Ozone
combination above the equator would have holes in the ionosphere the
size of Mars, instead of the size of the United States.

Another way of looking at it is that Freon is indeed heavier than air.
So is dust, so is salt, so is ice. All these things can reach high into
the atmosphere. We know when spring plowing happens in China, because a
fair amount of dust reaches us. Well, that freon is a lot lighter than
the dust. It can be stirred up by the wind, which is derived from sunlight.

Salt spray can also be measured in the stratosphere, and it is much
much heavier than Freon.

CO2 is also heavier than air, about 1.5 X air [at standard conditions].

What's missing from the observation are the effects of a turbulent atmosphere and the specific heat of both freon and CO2 molecules, among others.

In the absence of solar heating and air turbulence both CO2 and FREON would be hugging the earth's surface and we most likely would not be here [suffocated].

I'm not an atmospheric physicist, but I expect that both CO2 and Freon have three dimensional motion. They absorb energy from the sun at different rates [their specific heats and photon absorption cross sections are significantly different] and expand [become lighter in terms of grams/m^3 @ p=cons.]. Air also absorbs energy from the sun and expands. The three expansion rates are different and cause a 'general' lift to the individual gases. This 'lift' is not laminar, and therefore contributes to a turbulent atmosphere [AKA wind]. As part of the turbulent flow the heavier molecules are lifted to higher altitudes where they expand further [become lighter in terms of grams/M^3][Similar to clouds]. Eventually, the lift has insufficient buoyancy to sustain the heavier molecules and they start a drift back to earth. Some return to earth level. Others are caught in the updraft and re-cycle to a higher altitude [similar to a vortex phenomena].

My hypothesis, and qualitative description, would lead to a conclusion that a band, a thick layer, a region [similar to the E or F regions we are familiar with] of turbulent heavy gases of varying density forms above the sensible atmosphere and exhibits turbulent rotation similar to a vortex.

I'm ignorant here and this is just a hypothesis. If we have any atmospheric physicists or meteorologists on the list I would love to be properly instructed.

Well put, John.
I have understood the purpose of the 'matching network' for years, but
I have been puzzled by the source impedance expected on the generator
side.
I have several RF generators of various vintages in my collection and
most of the older tube ones have most peculiar output attenuators that
would have impedances that vary all over the place depending on the
setting of the output attenuator, frequency and, to some degree, output
cable length. On 'modern' generators, once you cut in 10dB or more of
attenuator, the output inpedance it pretty close to the specified, but
even many of them are quite a low impedance at 0 dB.
Perhaps someone with spice can characterize the output impedance of the
IRE network when fed from a generator of 0 ohm, 50 ohm, 75 ohm and,
say, 200 ohm output impedance.

Richard,

There is not such a mechanism in the general case, the example I gave
shows that the reflected wave does not necessarily travel back to the
source where it is absorbed.

If you re-read my words "Next thing, you will be thinking that the
reflected wave must travel back to the PA anode and will be absorbed
there causing overheating." Remembering the context was a wave on the
dipole reflected from the o/c end, and the word "must" was used to
mean "necessarily".

Sure,transmission lines with VSWR may transform impedance, have higher
losses (if they are long enough), operate at higher voltages in places
(if they are long enough), operate with higher currents in places (if
they are long enough). Nothing I have said is in conflict with that or
suggests otherwise.

Transmitters operated at other than their rated load impedance may
operate at higher voltages, higher currents, different power etc and
may damage components. Nothing I have said is in conflict with that or
suggests otherwise.

But, the mechanism is not that the reflected wave *necessarily*
travels all the way back to the PA anode by virtue of some kind of
momentum (as sometimes expressed by some amateurs).

In the case raised by the OP, the reflected wave on the dipole and the forward wave resolve (as in resolution of phasors) to an impedance of 50+j0 (OP's hypothetical example), and the constraints / conditions at the feedline / feedpoint junction are fully satisfied with no reflected wave on the feedline. (I used the term resolve, Cecil must call it destructive interference.) The reflected wave on the dipole does not have a momentum that *must* carry it to the PA anode to be absorbed there.

Owen

The definition of VSWR is the ratio of a voltage maximum to the
adjacent voltage minimum on the transmission line.

That definition might imply that VSWR cannot be directly measured at a
point, but it is possible to use a directional coupler to measure the
forward and reflected wave components in an very small region (wrt
wavelength) and to calculate the VSWR at that point (for all intents
and purposes).

Using a directional coupler / sampler, VSWR can be measured by this
indirect method anywhere along a transmission line by insertion of the
coupler / sampler.

It is reasonable to talk of VSWR at a point.

>end. The reflected wave (Say infinity:1 is NOT a

>will take on the sinusoidial of the wavelength
>for voltage (or current). Obviously, the reflected

No, you appear to have a misconception.

It is true that the reflected wave component is not constant with
displacement for a lossy line. The amplitude of the reflected wave
component decreases exponentially from the load end towards the source
end, and the rate at which it decreases is given by the line's

"matched line loss". The phase of the reflected wave component also changes with displacement (distance along the line).

The amplitude of the forward wave component decreases exponentially from the source end towards the load end, and the rate at which it decreases is given by the line's "matched line loss". The phase of the forward wave component also changes with displacement.

The resultant of these two travelling waves is the standing wave pattern that can be observed with a voltage probe.

You can find the derivation of SWR from those travelling waves in any reputable text book, I won't repeat it here.

On practical lines at HF and above with practical loads, the SWR decreases smoothly from the load to the source because of line loss, the lower the loss, the lower the rate at which SWR falls as you approach the source.

If you know the matched line loss and VSWR at one point, you can calculate the VSWR at any other point.

However, any amount of reflected power from the termination at the far end of a transmission line has a greater chance of damaging tx PA components, and of stress/failure to the transmission line itself than if the reflected power from the antenna/load was zero, regardless of the electrical length of said transmission line.

This reality of physics is not subject to debate, don't you agree?

Remember free-radicals? (not the jailed ones of the '60's)

Free radical Cl. can and does enter the atmosphere and it is a product
of the dissociation of freon. This is what destroys the ozone, IIRC.

Hoping my college course memory isn't too far off target.

If it makes you more comfortable to restrict your solutions to those
with flat lines (VSWR~=1) then that is ok with me, but that does not
invalidate other approaches. Antenna systems incorporating lines with
high VSWR do not necessarily subject the PA components to any
different risk, or transmission lines to excessive stresses, it is a
matter of design... and the design is more complex than buying a tx
intended for 50ohm load, some 50ohm coax and a 50ohm antenna and
plugging them all together.

NO! the defination is V(MAX) forward/ V(MAX)
reverse (at a given point)! That why they use 2
directional couplers (or one that rotates to
change directions , like BIRD)! Like 2 signals,
going in opposite directions, at the same freq,
at the same time!

Suppose I have a 50 ohm antenna fed with a one wavelength, 50 ohm transmission line. No reflected power, no damage.

Now I replace the 50 ohm one wavelength line with a 300 ohm one wavelength line. For 100 watts delivered to the load, the forward power on the line is 204 watts and the reverse power is 104 watts. All that reverse power could do a lot of damage, then?

So I guess I should replace the 50 ohm load with a 300 ohm one. Then there won't be any reflected power, and the transmitter should be ok. Right?

After all, it's physics.

I was thinking that maybe the efficiency of an antenna resonant at 3.5 MHz would be poor at 3.8 MHz where I want to use it. If there is no diminution of efficiency when the tuner fixes the impedance, then I'll just keep using it as is.

I built an I.R.E. dummy antenna recently to perform an alignment on a
Hallicrafters S-120. It is cobbled together on a small perfboard with
copper lands around the holes, has a length of coax with a male BNC
connector to go the the sig-gen and a female BNC connector to attach the
sig-gen lead.

I will post a pic on a.b.p.r when I can.

>Dee D. Flint, N8UZE

Sorry, but your wrong, my analogy is just fine for this subject. CW to a ham, like carpentry to a mechanic, can be useful BUT is NOT NECESSARY for each to do what they want to do effectively and properly.

Don't be one of those closed minds.

Yes, a ham CAN use CW if he wants and more power to him/her to do so. A mechanic CAN learn to be a carpenter if he wants to and more power to him/her to do so. But carpentry will not make a mechanic a better mechanic, no more than CW will make a ham operator a better ham operator. More useful to themselves and others, but NOT better.

Just because carpentry COULD maybe be useful to a mechanic does not mean that he should be required to learn carpentry to be a mechanic. A mechanic can be a damn good mechanic without picking up a hammer and a ham can be a damn good ham without touching a key.

I said it before and I'll say it again. 70 years ago a good mechanic needed carpentry skills but no more. 70 years ago a good ham needed to know code but no more. A code test for todays prospective hams is like a carpentry test for todays prospective mechanics.

You are correct to a certain extent on the 3rd party candidates, our home grown idiot, Jesse "The Mind" (his nickname for himself during the election) Ventura is a prime example. He "started" a 3rd party here, and dumped it after he got the governorship. He was as bad a governor as we've had, but since they've all been Democrats, including the Republicans, that's not surprising.

Both of the major parties are corrupt and don't give a rat's ass what the electorate wants once the votes are cast. There isn't a gnat's whisker difference between them when you look at what gets into law. On the court appointees, on the other hand, I might agree they are different.

I will still vote for anyone but the big 2. Any vote for them is wasted, any vote for anyone but them will at least show that some of us want change.

A vote for a Republicrat is a wasted vote. It just keeps the current crap in place.

Bruce,

I have some antenna system loss plots for a G5RV IV using different
types of feedline at http://www.vk1od.net/G5RV/index.htm .

There is a narrow optimal area around the 75/80m band, and the impact
depends on the length and grade of the coax used, ie the coax loss.
The exact frequency range will depend to some extent on your own
installation.

I would suggest that if you wanted to minimise the coax loss on
3.8MHz, you could adjust (shorten?) the dipole or the open wire
section, but that will also affect the other bands. Though it will
affect the other bands, the win on 3.8MHz might be worthwhile as the
antenna is less critical and lower loss on those higher bands on which
it performs reasonably.

Owen

PS: liked your pics, very impressive even when viewed at screen
resolution.

Pete, I was curious about the dummy antenna, too. Some time ago I modeled it and checked the impedance looking back into the output leads with a 50-ohm generator at the source. The results are here:

http://users.tns.net/~bb/dummy.htm

Before I did the model I figured that the dummy antenna was trying to simulate a certain length of wire on shortwave. But you can see that the magnitude of the output impedance (upper plot) is around 400 ohms throughout the shortwave part of the spectrum. Down in the broadcast band the network becomes almost purely capacitive, which is what a short wire will do.

In fact, at 500 and 1000 kHz (the two spots I checked), the dummy impedance is almost exactly that of a wire that runs 15 feet vertically and then 90 feet horizontally over perfectly conducting ground. I imagine they had a 100-foot wire in mind, a figure I think I've seen recommended for BC antenna length in the old days.

So I think the network is intended to be 400 ohms resistive at SW and at BC behave as a 100-foot wire would. I align radios with the network and then at installation I tweak the antenna capacitors, if they are easily accessible, on the actual antenna.

Brian

Hi Jim,

Are you so quick to impeach your Lecher line testimony from only one paragraph earlier? Owen's definition is perfectly correct, classic in fact. It may not be the only one, but historically (as in Lecher lines) it certainly preceeds yours by decades. However, it does suffer from accuracy (but that hardly vindicates the common Bruene circuit). There are at least half a dozen ways to measure SWR, each one being more appropriate for certain regions of the magnitude.

Some SWRs that are very low or very high would be impossible to measure using either method described above. Only academics are concerned with those methods. I've put my hand to most of them. I wasn't an academic, but NBS standards did demand their use. Some techniques are infinitely better than either described above (this presumes Owen's description consisting of a raw detector which introduces up to 23% error from square law problems).

No, you are quite confused / wrong. VSWR is *NOT* V(MAX) forward/
V(MAX) reverse (at a given point).

VSWR=|Vmax|/|Vmin|

VSWR=(|Vf|+|Vr|)/(|Vf|-|Vr|)

You seem to be mixing up the forward and reflected wave components,
and the resultant SWR pattern. You need to go back to the text books
and work it through.

Tom, Tom, Tom,

Is there some Libertarian weed you've been smoking? You can read tea leaves (leave aside ballots, because only Diebold machines can report that) on the basis of what is "said?" I'm afraid you are running a distant last against votes penned by me for low these 36 years.

As far as street people, no, I listened to them gush on about how they were going to vote for W. One fellow came up to me and leaned on my ear for an hour telling me how he was a soldier of fortune for Milosivic (OK, so I misspelled Ossama) in Bosnia (or Herzogovina or Toxiana) and fully expected to see W in another term. Then he and the rest would try to bum change (if that is what you mean by bribe), or a cigarette, and then left their empties nearby to take a dump in the alley.

They only differ from Rush Limburger by not being as fat, and they couldn't afford to shop doctors for prescription dope.

What was supremely ironic is that the state Republican party fought tooth and nail to evict them from the voting booth. Talk about taking the poison pill for the sake of political purity, this is like a Jim Jones kool-aid party to me.

No doubt, two years hence in the next election cycle I will be remembered as volunteering to hand out cyanide pills at the polling station. Would you care to be a reference so I can apply early?

> (I used the term resolve, Cecil must
> call it destructive interference.)

When two coherent waves superpose in an out-of-phase manner, it is called destructive interference. When two coherent waves superpose in an in-phase manner, it is called constructive interference.

100V at 0 deg superposed with 50V at 180 deg equals 50V at 0 deg. That's destructive interference.

100V at 0 deg superposed with 50V at 0 deg equals 150V at 0 deg. That's constructive interference.

One can solve a mental example. Assume a 1/4WL 600 ohm open stub made from resistance wire such that its impedance is 50 ohms. Apply a signal from a piece of 50 ohm coax and analyze the conditions at the physical 50/600 ohm impedance discontinuity. One will get a good idea of what goes on with a 1/2WL dipole at the feedpoint.

In fact, if one measures the forward power, Pfor, and the
reflected power, Pref, at a point on a transmission line,

SWR = [SQRT(Pfor) + SQRT(Pref)] / [SQRT(Pfor) - SQRT(Pref)]

If V(MAX) forward = 100V and V(MAX) reverse = 0V, then
the SWR is infinite?

If V(MAX) forward = 100V and V(MAX) reverse = 100V, then
the SWR is 1:1?

Doesn't that sound exactly backwards to you?

> reverse power could do a lot of damage, then?

Probably not at that power level but try this:

Let's say the power handling limit for the 300 ohm line is
1000 watts under matched line conditions. We are delivering
1000 watts to the 50 ohm load. The forward power on the 300
ohm line is 2040 watts and the reverse power on the 300 ohm
line is 1040 watts.

Yes indeed, the reflected power can cause the 300 ohm line
to burn up which is the point Richard Fry was trying to make.

A G5RV that is resonant at 3.5 MHz would suffer additional
losses at 3.8 MHz because of the higher SWR but the ham
listening on the other end probably wouldn't notice the
difference. But for 10m, the difference between 28 MHz
and 29.7 MHz could certainly be appreciable.

Try a 1000 pf silver mica cap across the twinlead at the
twinlead/coax junction just on 75m. I think you would
like the result.

Most of the street people around here are very conservative. I once knew
a homeless fellow who testified at a county supervisors meeting against

doing more for the homeless because it would bring in the riff-raff from other counties.
The drunken homeless, as opposed to the merely homeless, talk a conservative line because they think most people are conservative, and are more likely to give alms to a fellow Republican than to a traitorous Democrat.

Brian--

Your spice simulation looked familiar...VERY familiar. As it turns out,
I had plotted similar curves and happened to have used Microcap as well!
I was just not sure I understood the relationship between the transfer
function I saw and some kind of physical antenna.

Your comments make sense, though I do have one question: How did you
calculate the impedance of the antenna with the shape and dimensions
that you described?

Nice charts, thanks for doing those.

> So I think the network is intended to be 400 ohms resistive at
> SW and at BC behave as a 100-foot wire would.

Pretty much what I said initially. A uniform high impedance.
As others pointed out the output attenuator of most "service"
grade signal generators at the time was all over the place.

What I find amazing is that what we can do with Spice in a few
minutes was painstakingly done by hand until the they got the
results they desired. Then published as a "cook book" standard
for others to use.

The bottom line was that you could introduce a signal into the
receiver under test without undue de-tuning of the tuned circuits.

Quite true- the point I'm tryint to make is, that
when makeing swr measurements, that the APPARENT
measured swr, need have little/no relation to what
the true swr , depending on Where the swr is
measured in a line. at least with cheap meters.
and it really gets disconserting, when you
calibrate a SWR meter, (forward power , to the
set line, and then measure a reflected swr that is
Beyond the set line! Admittedly, much of that
is from too big a sampleing line, but it is
beyond the ability to have MORE power returned
to the source, than the source provided (perpetual
motion machine)! And, that you can prune a feed
line and lower your swr (measured), but that
doesn't change the load's mis-match, does it?
And that lines (1/4 wave, shorted, or 1/2 wave
open) form a very high impedence. Translation:
whatever is on that end of that line will repeat (ZL)
every 1/2 wavelength, will it not ? And , the
opposite would also be true (1/4 wave back, and
in odd multiples thereof, would this not show
a dead short (electrically), in a connected line?
Where am I wrong ? just curious -Jim

Did you know a reflection coefficient can be greater
than 1.0?

> that you can prune a feed
> line and lower your swr (measured), but that doesn't change the load's
> mis-match, does it?

If the Z0 of the feedline is different from the Z0
of the SWR meter, then the meter is not measuring
the SWR on the feedline.

> And that lines (1/4 wave, shorted, or 1/2 wave open) form a very high

The (virtual) impedance is (Vfor+Vref)/(Ifor-Iref)

The closer that Iref gets to Ifor, the lower the stub
losses and the higher the (virtual) impedance.

the scanning beam of butler arrays is affected by its antenna
"free-space" spacing.
im developing an 8-butler patch-based antenna array using an fr4 board
with er=4.2 and T=1.6mm with loss of .03...
im having problem with dimension so i squeezed the antenna element
spacing to its equivalent "guided" wavelength....
my questions are:how will this board guided spacing affects my
radiation pattern?i'd like to go for RT duroid boards with er=10.2 but
its very expensive..
any ideas to workaounr with my fr4 board?

thanks

Makes sense.
Also confirms my experience.
I've also found optimum performance driving the antenna where it's resonant
and matching the (purely resistive) impedances with a transformer.
In this case a simple toroidal autoformer. At 40 meters, a Tarheel
screwdriver with a five-foot whip is about 20 ohms, for example.

As you well know, the system change you describe will not remove all reflected power seen at the output of a tx expecting a 50 ohm load. You have simply moved the source of the reflection back to the plane of the tx output connector.

Under your scenario the transmission line is happy, but the tx - not so much.

Good stuff, Owen. Can the average SWR meter be
calibrated for the actual Z0 rather than for
50+j0 ohms?

> tx output connector.

Sometimes it helps to understand the situation by mentally
adding one wavelength of lossless feedline to the system.

Roy's suggestion to change to a 300 ohm load only apparently
eliminates the reflections.

XMTR---1/2WL 300 ohm feedline---300 ohm load

Mentally add the one wavelength of lossless 50 ohm line.
Conditions remain the same but the reflections are exposed.

XMTR--1WL 50 ohm feedline--+--1/2WL 300 ohm feedline--300 ohm load

There's a 6:1 SWR on the 1WL 50 ohm feedline and we have reflected
energy incident upon the source, just as you described above.

Pete, I forgot to mention the reason I believe the IRE dummy antenna tries to look like a 400-ohm resistive load at shortwave instead of a certain length of wire. You can see why here:

http://users.tns.net/~bb/antlen.gif

This is an old RCA chart showing the behavior of an end-fed wire for lengths to 125 feet. It indicates the many resonances and antiresonances a short wire can exhibit. Since the antenna impedance and the resulting performance vary so markedly with wire length, and because it would be unrealistic to expect all listeners to use one particular length, I think the dummy antenna is just intended to roughly match the input impedance of a typical radio. I'm not sure about consumer radios, but old communications receivers all seem to have a specified input impedance of either 300 or 400 ohms.

On the broadcast band, any wire shorter than about 150 feet will look capacitive. It won't exhibit the resonances you see in the chart at shortwave. So even if the wire is shorter than the 100-foot length the dummy antenna seems to model and exhibits a higher capacitive reactance, it won't affect the radio's RF tracking that much. On the broadcast band, most radios seem to use rather loose antenna coupling to minimize mistracking. This allows them to accomodate antennas of various length. There is an interesting discussion about antenna coupling strategies in the Radiotron Designer's Handbook.

We must always remember the #1 rule for POLITICIANS: "In everything you do, ALWAYS campaign for re-election." A politicians #1 job is to get re-elected!

Trying to contribute to the public good means making political decisions, and political decisions make political enemies and possible loss of an election.

Therefore, follow the 2nd rule for POLITICIANS: "Say YES to everyone as you campaign, but vote for nothing that is controversial."

Message-ID: <njvtf2l6cm3lvsj0no47i70vmk4mf2cmo3@4ax.com>
Source record: 53012

The exciting news I have is that I decided to buy a discone antenna matching my IC PCR1500 wideband receiver. Getting an AOR DS3000A, "capable of covering 75 to 3000 MHz. . . . It is only 2.9 feet (0.87m) tall and weighs 1.55 Lbs. This antenna can be used for transmit on 144, 430, 904 and 1200 MHz ham bands (under 50 watts)."

Comes with a cable using N connectors, so now I have to decide on using an adapter going from N to BNC plug or soldering on the BNC connector I need. Or I could probably get a good cable with the right connectors at eBay.

Cost from Universal Radio was $126, which seems like a lot, but I did my homework narrowing down the choices from WinRadio, which was the only other covering the range my receiver can pull in, and a couple others with use extending only to 1300 MHz.

Just gonna use my rig in an apartment, so the small antenna will just be like a Christmas tree in the corner. Robinson Carusoe

Hi Owen,

Interpretative comment - You state here "theoretical" plots of a model. At the reference you state "indicated forward power, reflected power." To me this implies data taken, not generated from a model's formula - but my interpretation may be a stretch.

Data source comment - However, you go to rather elaborate lengths to specify a load of 2+0.5j (sic) and a line of 50.36571-j0.17872. What was the point of injecting reactances here if you simply wish to illustrate the degradation of SWR with feedline loss? They add to the implication of data taken, not generated - except for 5 place resolution at 100 MHz which is (excuse me) absurd.

Elaboration of the implications of interpretation and data source comment - Further implying this was data taken at the bench is the declaration "THE REFLECTOMETER IS NOT CALIBRATED FOR THE LINE Zo." Again, my presumption circuits peg on that one because the reactances are so easily removed from emphatic concern if you are in control of the "virtual" workspace.

Informational comment - What is supposed to be the total length of line? Was it matched at its input, or simply fed by a transmitter?

Picky comment - Graph font sizes are a squint too small.

Last, really picky comment - Your copyright notice at the bottom is off by a year.

You got me, I don't have the experience to know what I'm doing. Other antennas, more expensive and heavy, can cover from 300-4000 MHz, but I was reacting to negative comments about Radio Shack and a couple others that are a lot less expensive, as low as $30 on eBay. One opinion I read is that those advertised as going only to 1300 MHz can actually function higher.

Subject: Mobilantenne oder Festantenne

Hallo Felix,
nach unserem tollen QSO auf 160m waren Peter (DL1BLD) und ich (Heino,
DJ5ER)
total erstaunt mit welch einer tollen Feldstaerke Du in Bremen
angekommen bist.
Wie man eine solche Antenne bauen kann moechten wir gerne wissen (auch
fuer die
anderen KW-Baender).

73 aus Bremen von Peter (DL1BLD) und Heino - DJ5ER

Translation:

Hello Felix,
after our fantastic QSO on 160m we (Peter,DL1BLD)
and I (Heino, DJ5ER) we were completely surprised
with what a strong field strength you arrived in Bremen.
We would like to know how such an antenna can
be built (also for the other HF bands).

73 from Bremen .... (QRB = 600 Km)

5th September 2006:
Now I have reduced the length of the radiator to 2m = 1.25% of the
wavelength,
and I still get the same good reports, as can be seen on the email I
received after a few
fine contacts last night. Still with 60W PEP, at the border of the
city, antenna mounted on the car:

Hello Felix.
Congratulations for your antenna work.
You are the first mobile station on 160 meters for me.
Even you are stronger as the Germans on 160 meters.
I give you on 1.862 Mhz S 9+15 db in the peak!!
The background noise level was S 8 during our QSO

Hope to meet you agn for next report and test.

Piet Schipper / PA0QRS (near Rotterdam)

Schipper mobiele Telecom
2931 LH Krimpen a/d Lek

Such experiences show, that you can transmit with this small antenna
as effective, as with a 60m long wire, up in the air.

This is possible with:
- Radiating planes and not wires
- Differential feeding system
- Elaborated grounding system to minimise ground loss
- Perfect, low loss matching of antenna radiation resistance

With best 73s

Felix HB9ABX

It is true that reflection coefficient can be greater than 1.0.

The reflection coefficient *CANNOT* be greater than 1.0 where Zo is
purely resistive.

So, where a sampler is calibrated (nulled) on a purely resistive load
(eg 50+j0) as is most commonly done, it should never show a reflection
coefficient greater than 1. A reflectometer calibrated to a resistive
load and that shows a "reflected" reading greater than the "set"
reading is inaccurate / defective / a poor design.

Yes, a reflection coefficient greater than one is caused
by the interaction of the Z0 reactance and the load reactance
in an effect resembling resonance.

For avoidance of any doubt, it is entirely theoretical. Line
characteristics are based on an RLGC model of the line derived from
Belden's published specs for 8262 (RG58C/U).

Firstly, I should not have said "indicated forward power, reflected
power" as the "indicated" value is a voltage or current, ie the square
root of power, it is the deflection on the indicator meter if you
like, the meter current on the reflectometer. I have changed the text.

The meaning "indicated" is that it is the voltage or current driving a
reflectometer meter, calculated from the sampler and line conditions.

The stated line Zo precision is a result of lazy cutting and pasting,
and it should not be seen to imply that level of accuracy. I have
changed it.

The load (2+0.5j) is relatively unimportant, but it was a load to create a high VSWR, higher than would be practical for such a feedline at that frequency, extreme to satisfy the people who assert strange things can only be observed at extreme VSWR. The reactance is just a non zero value for no other reason than to test the models behaviour on a complex load.

What is significant, is the load VSWR is very high at ~25, I would suggest higher than practical, and therefore extreme.

A reality of lossy lines is that Zo is not purely resistive.

A source of instrument error is a sampler that is calibrated for a nominal Zo (being Ro). Fig 1 shows the modelled VSWR (which is what accounts for increased loss, impedance transformation etc), and Fig 2 shows the calculated indication for a reflectometer calibrated or nulled at 50+j0. There is a small difference, and the difference becomes minute at lower VSWR.

>
>Informational comment - What is supposed to be the total length of
>line? Was it matched at its input, or simply fed by a transmitter?

The x scale is in wavelengths (as noted on the page), Frequency is 100MHz, line length covered by the graph is therefore about 9m.

>
>Picky comment - Graph font sizes are a squint too small.

Ok, it is a quick cut and paste from Mathcad. For a permanent article, I would try to do better, for I too have aging eyesight!

>
>Last, really picky comment - Your copyright notice at the bottom is
>off by a year.

Thanks, I have fixed the footer (which is common for most of the site).

The graphs are a quick and dirty presentation, but it is a very detailed transmission line model underneath. I acknowledge there are all sorts of error sources in real life, but keeping sight of the underlying phenomena helps to flag whether measurements look invalid.

Back to the original proposition that asserted that changing feedline length can vary measured VSWR dramatically, and that shortening a feedline might improve VSWR, there are reasons why that might happen,

but it is not explained solely by what is happening on the inside of the feedline. A possible explanation for example is that the feedline is not decoupled and carries common mode current, and that changing the feedline length changes the load impedance seen by the load end of the transmission line.

So, enough from me, can someone produce details of a scenario with a very high load VSWR where there are multiple sweet spots with 1:1 VSWR on a practical line? ("VSWR" here means a property of the line at that point, not what might be read by an unsuitable or defective instrument, and an extremely long line is not "practical".)

Thanks...
Owen

First time I noticed this was in the early 70s after I put a CB radio
on a school bus camper. The same radio and antenna had been on a
Volkswagon before. The difference was very noticable.

That must have been an increase in surface area for the ground side of
things of something like an order of magnitude.
I bet it was a striking difference.

Typical samplers derive a voltage sample and a current sample in a small region approaching a point for all intents and purposes. The current sample is converted to a voltage (by passing it through an impedance, and added algebraically to the voltage sample. The resultant RF voltage is rectified and fed to a voltmeter.

If the impedance used to convert the current sample to a voltage is purely resistive, and assuming the sampling process does not introduce any differential phase shifts, then such an instrument can only be nulled for a purely resistive Zo. If that conversion impedance were complex and adjustable, then it would be possible to null the instrument on practical values of complex Zo.

However, under a linear RLGC model, Zo varies with frequency, both Xo and to a lesser extent Ro (see the graphs at http://www.vk1od.net/tl/tllc.php).

So, nulling the instrument on nominal Zo (Ro) makes sense, but just keep in mind a small contribution to error and an explanation for why measurements might not agree with a Zo=Ro model. I do recall someone insisting that reflection coefficient cannot be greater than 1 because a Bird 43 would never measure such. He was right, the Bird 43 should never indicate such, but not because reflection coefficient cannot be greater than 1 in the general case, but that the sampler is calibrated (nulled) for a Zo=Ro scenario.

The discussion about using a 50ohm VSWR meter in a practical line where Zo is not exactly 50 ohms was just to acknowledge that there is error introduced, that it can be estimated, and that it is low at low VSWR values and will be likely to be lost in other measurement noise due to lots of other variables.

Well, had I responded earlier, I'd have suggested the Diamond DJ-130.... well made, goes for about $100, but as you have mentioned already, only is spec'd for an upper end of 1300 MHz. But then again, I can not think of any voice traffic that you would find beyond about 900MHz area, anyway. Good luck.

Thanks, Owen, and all and sorry to cause so much
grief. I fall on my sword! Have believed 99.44%
of what was in the old VHF'er Magazine, as was
started by a consortium of many engineers ,
originally by Doug Demaw, W8HHS, as editor, and
finally Loren Parks,K7AAD, an ex engineer from
Tektronix, and covered the Gamut of VHF, UHF, and
Microwave-- to early satelites and Moonbounce.
Was instrumental to me getting on air, many
moons ago. Tho much I've learned (and much I've
forgotten!) over the years. I have built tuned
coaxial finals, ect., and from former job,
haveing to use tuned lines (mainly,to couple
cavities together , and then tune them to
use on same antenna. IF those lines changed,
the things detunewhen you remove your test
equipment! Also, I get a little bull headded
after all theses years! Stuck on Stupid, if you
might! Owen- your charts are quite illuminating!
and, finely, The meter referred to , if memory
serves correct, was made by SWAN, just before
they went out of business (made for the "CB"
trade, more than amateur radio. and the lines
used in it were on a Printed Circuit board!
and this probably before they knew how to get
the correct impedence , on a p.c. board!
I shall return to my lair-- Jim NN7K

When you have to spend time building a skill, you spend more time learning other related things as well. Hams that haven't had to study to pass a 13 wpm CW exam, probably don't know the written portion of the exam as will as hams that did. If I hadn't had to pass 20 wpm for my Extra, I would have taken the exam a lot sooner, but as I had to build my CW abilities, I also spend more time learning the theory too. It made me a better ham.

You people don't want knowledgable hams anymore. CB'ers dont have to learn CW, are they better?

No need for that Jim, the discussion has challenged your thinking (and mine), and that is part of the learning process.

>of what was in the old VHF'er Magazine, as was

IMHO, it is not a very good article.

Forward Voltage, Forward Current, Reflected Voltage, Reflected Current, Current, Voltage, Zo, VSWR, impedance and propagation constant are all relevant, related but different and the article doesn't adequately draw the distinction.

Indicators might sample one or more of voltage, or current, or directional power. They are all different, a voltage sensor or a current sensor alone at a single point will not allow you to determine VSWR, a pair of directional power sensors will. Your Lecher lines example needs a voltage or current sensor, not a directional power sensor (which won't work), whereas a VSWR meter needs a pair of directional power sensors, not a voltage or current sensor (which won't work).

My view is that the article is imprecise, confused and contains bad advice. It does play to one of the archetypal myths of ham radio!

I am considering whether I should create some more graphs of current, voltage, and impedance etc that illustrate how those behave, and incorporate it in a more complete permanent article on my web site. (IIRC there were some graphs of voltage, current, phase in Fred Terman's book, but I am thinking of going a little beyond that.)

Thanks for the response Jim.

Tom,-Richard, Tom-Richard, Tom-Richard....

In this imperfect world, one is perhaps foolish to expect perfection. I don't-you shouldn't.

While we all accuse each other of being Democreeps, or Republi-cant's, or even perhaps the ultimate pejorative - Liberal, it is perhaps a more realistic expectation to just settle for competency.

That would be kewl.

Ive had trouble with this type of antenna too. Turning the shield inside out over the feedline is not a good idea. The outer viynl jacket has some very poor RF characteristics not to mention it is a bear to do. Stangely enough plans for this antenna abound. Shakespeare used to build a CB antenna lie this called the big stick They latter change it to four wires inside a fibergas tube with th wires imbedded in the fiberglass connected to the shield of the feedline. Then the feedline is centered in the tube using styrofoam. I built something similar using a metal tube connecting to the shield with the coax down the middle of the tube also using little pieces of styrofam to center the cable in the tube. This seemed to work pretty good.

Was code the ONLY way to learn the written portion? Besides, using a
bunch of beeps to spell out characters over the airwaves takes no
technical ability at all. Here in Canada, a no-code license requires
MORE technical skill than a code license. In other words, here in
Canada you need to learn MORE to pass a no-code license since learning
code is a motor skill, not a technical one.

>You people don't want knowledgable hams anymore.

Learning code does not impart any type of "knowledge" any more than
learning roller skating.

>CB'ers dont have to
>learn CW, are they better?

Based on the CBers I used to hear on the higher sideband channels, I
heard very little of the insults I have seen here spewed by some of
the pro-coders. Therefore, I'd say that they were at least better
behaved than the aforementioned pro-coders.

Yes, there were assholes on CB, but CB didn't make them that way. By
the same token, learning code will not turn an asshole into a nice
guy. CB is just a ham radio in the embryo stage, a zygote. The only
real difference between CB and ham is the choices of bands and the
power of the transmitter, when you really look at things in the most
basic sense.

Agreed. But, please remember that Blow Code is a morse bigot.
He (or she) is representative of only a minority of United
States radio amateurs. When the major accomplishment in life
of such morse bigots has been morsemanship, they will naturally
trumpet that singular skill and attempt to moralize it as some
kind of positive attribute that one MUST have.

>Here in Canada, a no-code license requires
>MORE technical skill than a code license. In other words, here in
>Canada you need to learn MORE to pass a no-code license since learning
>code is a motor skill, not a technical one.

I applaud Industry Canada's decision on their regulations.
My contact with Canadian regulations has been minimal but
their website on radio regulations explained it all. Blow
Code is confused on the task of the United States FCC in
regulating ALL US civil radio; our FCC is not a booster
organization for amateur radio or any other radio service
here. The FCC only "wants" radio service users to obey the
regulations.

Manual radiotelegraphy skill testing for an amateur radio
license has existed since the first US radio regulating
agency and was maintained mostly out of inertia and the
insistence of the ARRL (once it had risen above its
competition) through lobbying the FCC. Given the vast
scope of today's radio services, the FCC has a far greater
task to keep up with its regulatory task. Amateur radio
here is low on the regulatory task list of the FCC.

Manual telegraphy IS a motor skill (more correct "psycho-
motor" skill) but morse bigots become more psycho about
their personal skills, equating it to intellectual
knowledge and the ability to reason. Morse bigots see
only their kind and want to destroy those who think
differently; that is security for their "tribe."

>>You people don't want knowledgable hams anymore.
>
>Learning code does not impart any type of "knowledge" any more than

>Based on the CBers I used to hear on the higher sideband channels, I
>heard very little of the insults I have seen here spewed by some of
>the pro-coders. Therefore, I'd say that they were at least better
>behaved than the aforementioned pro-coders.

The gratuitous insults to Citizens Band Radio Service
users has been in existance since 1958 when the USA
authorized its use here (as 'Class D' CB on only 23
27 MHz band channels). That's a time span of 48 years.

From its inception CB has NEVER required ANY testing
to obtain a CB license. The "license" was pro-forma,
a slight revision of the Restricted Class of Radio-
telephone Operator license then common to services
such as both private and civil aviation pilots.

Nearly a half century ago, US radio amateurs developed
a distaste for the US government and these new radio
service users for: (1) "Taking away" their 11 meter
band (little used, sitting below the largest amateur
radio allocation on HF); having the audacity in NOT
requiring any testing plus intolerant bitching over
NOT having to pass any morse code test. That almost-
hatred developed into the bigotry seen today.

The bigotry grew when about a decade after authorization
the offshore electronics industries hit the US market
with less-expensive CB transceivers and long-haul truckers

took to that service. CB users here soon out-numbered
radio amateurs by a large margin. With such a huge base
of users, a common patois/lingo/jargon grew that was NOT
related to amateur radio but had roots in our state
highway patrol police organizations. That lingo became
quite different than amateurs' use of theirs, so that
reinforced the "different-destroy" attitude of the
amateurs' bigotry against CB users. Amateurs like to
make fun of CB lingo but don't realize their jargon is
amusing to other HF radio service users and the military
radio. Amateurs tend to think of themselves as first
and foremost without realizing that they never were
first nor foremost and were always a minority in radio.

>Yes, there were assholes on CB, but CB didn't make them that way. By
>the same token, learning code will not turn an asshole into a nice
>guy.

Morse bigots have the egotistical self-definition of
THEIR skills being the only "true" ones for amateur
radio. They will rationalize that self-righteous
attitude with any number of archaic "reasons" that
defy validity for regulatory purposes by radio
regulating agencies. In last year's Notice of
Proposed Rule Making (NPRM) on the elimination of
morse code testing for US radio amateurs, several
Commenters cited the ability to "thwart terrorism"
by using morse code! :-) Apparently they had taken
a Hollywood motion picture fictional depiction of
aliens-from-outer-space-invasion as a documentary of
a real event [film title was "Independence Day"]!

>CB is just a ham radio in the embryo stage, a zygote. The only
>real difference between CB and ham is the choices of bands and the
>power of the transmitter, when you really look at things in the most
>basic sense.

I see it differently. Human beings like to communicate.
That is evident in the enormous growth of cellular
telephony and daily use of that; the US Census Bureau
stated two years ago the one in three Americans had a
cell phone subscription. That is roughly 100 million
users of those tiny full-duplex radio transceivers.
Several million CB users exist on USA highways (exact
figures unknown as CB has been unlicensed for years,
but can be approximated from EIA - Electronic Industry
Association - statistics on manufactured and imported
electronic equipment). FRS and GMRS unlicensed UHF
HTs may exceed the million mark by now. In the maritime
radio service private boat owners' VHF radios exceed
that of commercial ship owners, VHF voice required on

inland waterways and harbors for traffic control.
Private boat owners are increasing their HF radio use
on deep-water travels unsing HF SSB voice (a few radios
marketed for sales to both them and radio amateurs).

CB is 48 years old, hardly a youngster/child/teener.
It is DIFFERENT than amateur radio on HF, therefore
abhored by some radio amateurs stuck in their radio
bigotry attitudes put there long ago by their
ancestors. If truck drivers have spread a DIFFERENT
lingo on CB radio, then they did so out of THEIR need
to communicate about THEIR things, not some self-
righteous and not-required-by-regulation "traditional"
lingo used by hams. Amateurs don't/can't speak to
others on HF and are restricted (in the USA) to
"non-essential" communications (paraphrased from US
regulations). Truck drivers CAN and DO communicate
with others on and off the highways freely and with
much less of the bigotry displayed by some radio
amateurs looking for someone to destroy.

Where does manual radiotelegraphy fit into this?
It doesn't.

There are two ways to communicate when all you have is a transceiver, phone, & CW. All you need for phone is a microphone, All you need for CW is a pencil and paper. If you had to build a transmitter in an emergency, a CW transmitter is simpliest to build. We are after all technical aren't we? We're not just appliance operators.

Eliminating CW removes a way we can communicate. A simple way, where all that's required is an ear, a pencil, and paper, and a skill.

GREAT info, that's why I lurk here often.

Just one teensy question, though...is this polarized?,
e.g. the 200pf cap is the receiver probe, the inductor
plus shunt is the signal gen connection? or versa-vice?

Thanks,
Terry Bakowski

[see you at the Peoria Superfest]

>There are two ways to communicate when all you have is a transceiver,
>phone, & CW.

WRONG, WRONG, WRONG...

It is voice, radiotelegraphy, data, pulse, right off the bat,
plus a few others which you have NO idea they existed for
EMERGENCIES.

Blowcode, you are stuck on HF ham thinking. So were some
other morse zealots and morse bigots in this forum many
years ago. Their scenarios were invalid comic-book stuff
then and now you've just repeated the same. Deja phooey.

On HF you can find some EMERGENCY calling frequencies...but
those aren't on ham bands. I recall only two, one for
maritime, one for civil aviation over-ocean routes. Aviation
has some more but you aren't worth the time to go look them
up in the huge Part 2 regulations of Title 47 C.F.R. Both
are VOICE.

Over or near land the aviation VHF frequency is 121.5 MHz.
Military aviation is 243 MHz. Both are VOICE. Airborne
transponders (those are transmitter-receivers) has a
"squawk" code just for emergencies and, in a pinch, you
can push the IDENT button. Transponder output will auto-
matically show up on ATCRBS radar displays. The little
HTs in military parachute backpacks can do both VOICE
and DME/TACAN (the 'pulse' I mentioned). [you probably
don't know what DME or TACAN are yet they've been around
for a half century.

On waterways (not open ocean) there are VHF frequencies
for EMERGENCIES. VOICE. Go look those up in Part 2.
VHF VOICE is used in the USA in harbors and inland
waterways. Need EMERGENCY frequencies on land? Plenty
of those, band specific, organization specific, freqs
available if you are serious about having to use them.
Those frequencies are kept open 24/7 in most areas and
have emergency power backup. Three major land PLMRS

bands, can you name them? [I didn't think so]

Ever hear of a cellular telephone? By now, I'll bet you
noticed them. One in three Americans have one. Little
1 GHz HTs with lots of added features with tens of
thousands of cell sites to connect to telco. You can
punch up nine-one-one on them same as a wireline phone.
Nine-one-one is operated 24/7, done by professionals.
Cell sites and telephone exchanges all have "floating"
emergency power, can remain operating on AC power outage.

Think you can call for a paramedic with your little "CW"
transceiver, Blowcode? Or a fire truck? Police car?
Sorry, Blowcode, they use VOICE and above 30 MHz.
Some paramedic ambulances have EKG instruments with
radio coupling to a hospital. Some police departments
have data terminals IN their cars (LAPD does as do
many adjacent incorporated cities here).

>All you need for phone is a microphone, All you need for CW
>is a pencil and paper.

BWAAAAAHAAAA!!!!! How are you on "straight wire CW"
Blowcode? Can you do 'twenty' just rubbing two bare
wires together? [remember, you have to scrape OFF
the insulation to make contact...]

>If you had to build a transmitter in an emergency,
>a CW transmitter is simpliest to build.

!!!BUILD?!?!?!??? BWAAAAHAHAHAHAHAH!!!!!!!!!!!

Is your QST featuring the "Tuna Tin Two" handy and able
to survive a full EMERGENCY environment? Do you have
the parts? Do you have a power-less soldering iron?
Do you know how to use hand tools? [I don't think so]

Once you've cobbled together something that MIGHT work,
HOW DO YOU KNOW? Did you have test equipment that
survived the EMERGENCY, Blowcode? [I'll bet you think
so] How do you know you're on a frequency that you
think is good for emergencies? You do "laying on of
hands" to miraculously make it work? In this (unspecified)
EMERGENCY do you have two functioning hands to use the
tools to 'make' this thing? Will you need AC power
to run it? Will it work on DC? From where will the
electrical power come from? Rub two Handbooks together?
Cobbling together a one-tube transmitter MIGHT be
possible, provided you have plans, the parts, a
suitable tube, and the right values of components
(which you seem to think you 'know' exactly?. It might
take 24 hours or so...at which time the "emergency"
would be over and the 'emergency' victims might be

long dead.

You can spout bullshit bragging only so far. You've
gone too far, Blowcode. You DEMONSTRATE that you can
cobble together a simple 'transmitter' out of a pile
of parts which do NOT know of ahead of time. SHOW US
or someone. Put your money where your big mouth is.

Here's what the right-thinking folks do: Have a radio
or radios ALREADY available for emergencies, along with
a power source, on some 'emergency frequency' that you
KNOW WILL BE HEARD. The "CW-saves-the-day" scenario is
BS that went out before the GMDSS was activated seven
years ago; the USCG is NOT monitoring the 500 KHz "CW"
frequency and neither are many other equivalent national
maritime aid agencies. A few years ago a gal teenager
picked up a call for help on an FRS HT from a stranded
mountain climbing team...voice, not "CW", miles away.
Made the Washington and Oregon newspapers. [FRS isn't
on ham bands, Blowcode, and the gal wasn't a "radio op"]

>We are after all technical aren't we?

You (sure as hell) sound like you can barely wire up
a doorbell. With a QST article on it to show you how.

>We're not just appliance operators.

Right...in addition you are an unthinking nuisance.

>Eliminating CW removes a way we can communicate.

Eliminating a code test does NOT "remove its use."

If morsemanship is so damn good, it DOESN'T NEED
TESTING. Folks will take to it without needing to be
tested if its such a wonderful thing.

>A simple way, where all
>that's required is an ear, a pencil, and paper, and a skill.

Blowcode, you need a SKULL more than a skill...one
with a working brain inside it. Try to get a new brain. Quickly.

Now go back to reading those comic books from the ARRL.
You know, the "Archie" ones that you saved up long ago.

Newsflash: ALL radio operators, code or no-code, are "appliance
operators" as you colloquially state. A radio is a means to
communicate. Knowing code just adds another way to use that radio.

There is NOTHING about removing code testing that will stop you from
using code. Wanna use code? Go ahead, knock yourself out. You can
hammer on that key all night long, for all anybody cares. Hammer on it
in your sleep. Hammer on it in the shower.

Just don't tell me that I am a bad person if I don't.

3930. Source matching influence on line VSWR

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-08 06:11:30 UTC
From: Owen Duffy <owen@no.where>
Message-ID: <j012g2p2sch41ch4q492ii7f6l47dd40fd@4ax.com>
Source record: 52967

It has been suggested that steady state VSWR measurements on a transmission line are influenced by the source to line match, and that the measurements are not valid unless the source is matched to the line.

That seems in conflict with textbooks that suggest that the reflected wave is entirely determined by the conditions at the load end of the line, and that the conditions at any point x on the line can be determined from x, Zo, the load impedance, and the line's propagation constant.

So, I have performed a small experiment.

I have a tx - 1m of RG58 - T-match ATU - 1m of RG58 - MFJ949E ATU - 20m RG6 - dipole.

The MFJ949E incorporates a crossed needle VSWR meter, and is used in the 'thru mode, so it is just a VSWR meter.

I have tried tests at three frequencies where the VSWR meter on the ATU indicated 1.1, 2 and 6, and tuned the first ATU for low VSWR on the tx's inbuilt VSWR meter. Some would suggest that this means that the tx is matched to 50 ohms, but I am not endorsing that view. I have then varied the ATU's output capacitor over its full range, and although the '949E's needles vary, they always cross on the same VSWR line. (I have only considered readings where the needles are upscale of 30% for accuracy reasons).

In this experiment, the large variations that I made in source impedance did not noticeably influence the measured VSWR at low, medium and high VSWR readings. The observations would not suggest that steady state VSWR is influenced by the source impedance.

Comments?

Owen

Even if the no-code ticket was made 6 months or 2 years
in active length it would not matter one bit. Amateur radio
in the public eye is unknown and your average young person
is far more interested in the Internet, online video, instant text
messaging and cellphones. There are too many commercially
available technologies, which are far cheaper I may add, than
amateur radio which while a curosity is still a functionally and
technologically obsolete pursuit. Sorry but that's the truth.

> Comments?

If it isn't obvious from the math in the textbooks, it's simple to see from an intuitive standpoint that the source match has no effect on the SWR. Here's why:

Imagine a system where an AC voltage source, turned off, is connected to a transmission line through some arbitrary resistance. The other end of the transmission line is connected to some arbitrary load. When the source is first energized, a wave will travel from the source end of the line to the load, where some of it will be reflected. The fraction reflected, and its angle, are determined by the relationship between the load Z and the line Z0, and this ratio is in fact the reflection coefficient at the load end.

We now have forward and reverse waves on the line, one of each, which sum to form the standing wave, and from which we can calculate a standing wave ratio. When the reverse traveling wave reaches the input end of the line, some fraction of it will be re-reflected toward the load, the fraction depending on the mismatch at the source. And here's the key concept: No matter how much is re-reflected toward the load, the same fraction of that new forward traveling wave will be reflected from the load as was reflected when the original forward wave hit the load. So the total of the two waves traveling forward divided by the total of the two waves traveling rearward is the same as when we only had one wave going each way. Consequently, the SWR is the same as it was for the first two waves. You can continue this process until the magnitude of each new wave is insignificant or, in other words, steady state is reached. Each pair of new waves makes no change in the SWR. And all this

is true regardless of what fraction is reflected at the source end of the line.

Let's just put some numbers on things as a simple example. Suppose the source reflection coefficient (the source Z as seen from the line) is 0.5, and the load reflection coefficient is 0.3. (I'll assume a line that's an even number of wavelengths long and reflection coefficients which are purely real to avoid bothering keeping track of phase angles.) And suppose the source has an amplitude such that the initial forward voltage wave is exactly 1 volt. The first forward wave then has an amplitude of 1 volt, and when it hits the load, a rearward moving wave of 0.3 volt is created, resulting in a reverse/forward voltage wave ratio of 0.3 and an SWR of 1.86. When the 0.3 volt rearward traveling wave reflects off the source, it creates a new forward wave of 0.3 * 0.5 = 0.15 volt. And when this hits the far end, it sends back a wave of 0.15 * 0.3 = 0.045 volt. We now have 1 + 0.15 volts going forward and 0.3 + 0.045 volts going rearward, or a total of 1.15 volts forward and 0.345 volts reverse. The reverse/forward ratio is still exactly 0.3, and the SWR still 1.86. You can continue this for any number of forward-reverse pairs and always get the same result. And you can substitute any value you'd like for the source reflection coefficient, and also get the same result as long as you don't change the load reflection coefficient.

A moment's thought reveals that if the cable is lossy, the same fraction of each forward wave still returns to the source, so the same reasoning can be used to get the same result -- that is, that the SWR is still unaffected by the source match.

The problem with doing experiments to "prove" a well-known principle is that it's often very difficult to get good experimental results. So when the results don't agree with the established theory, too many experimenters become convinced that they've disproved the principle. What they should be doing is figuring out what went wrong with the experimental measurements.

In this case, I'm relieved that the experiment does agree with the theory which has been established, used, and proved for more than a century rather than with amateur folklore. If it hadn't, it would have proved only that the experiment was faulty.

How about a USA version of the Canadian solution:

1) No change to license classes.

2) Tech requires Element 2 (Tech written) same as now.

3) General requires a Tech license plus Elements 1 and 3 (5 wpm code, General written). If Element 3 is passed with 85% or better correct, credit is given for Element 1.

4) Extra requires a General or Advanced plus Element 4 (Extra written).

No new tests. No extra paperwork other than the VEs determining whether someone passed Element 3 with 74% or 85%. No reduction in requirements, just an alternate path.

Why not?

Pete, I remove temporary items from my web site pretty quickly due to space restrictions. I tried to e-mail the chart to you but got the following reply:

----- The following addresses had permanent fatal errors -----
<hpf@gainbroadband.com>
(reason: 591 your host [216.86.143.7] is blacklisted by bl.spamcop.net. No mail will be accepted)

No more midnight spam for me! Anyway, the chart is back up for a couple more days.

By the way, on the perfboard I used to build my dummy antenna I added a 0.1 uF coupling capacitor between the signal generator input and a second output lead with an alligator clip. This provides a 50-ohm DC-isolated signal for IF alignment. I usually align radio IFs by sweeping a signal at the front end, often just blasting through the RF and mixer stages at 455 kHz. But the alligator clip is handy when I want to drive the mixer grid directly. You can drive the grid with the dummy network, but the 50-ohm source impedance of the direct output ensures that the parallel impedance at the grid doesn't affect the sweep flatness.

Owen, believe what Roy just said, because it's true. In fact it's the best explanation of the concept that I've ever read.

Do you have Johnson's "Transmission Lines and Networks"? He was chairman of the EE Dept at Princeton. On Page 100 he says, 'The steady-state ratio E+/E- is defined as the reflection coefficient 'k'...The ratio is determined only by the load and the line, not by the generator. It is completely unaffected by the quantity 'kg', which is the coefficient seen by an individual backward-traveling wave as it reaches the generator terminals. The latter affects the steady-state solution only through its influence on the sending end voltage, i.e, through its influence on the magnitude of the entire solution."

Hope his nips any new myth in the bud.

Walt, W2DU

AMERICA IN DANGER of its own out-of-control Bio-Terror:
Is 1984 here? Or cripping... God help us,
blinded!
Originally Secret Bio-Aerosols are misused to HARM and Torture in
U.S.A.

Our government needs TORTURE in U.S.? See details
below...
It has your VOTE, support? Abused...

CRITICS (political/social/cultural) are harassed and secretly
persecuted
along with their KIDS in schools/colleges, especially, during
tests/exams
(Think: Guantanamo "stress-positions" in the context of
1984-technologies)

Bio-Aerosols and aerosolized chemicals are used to cause:
- severe colds/coughs turning into bronchitis, eye irritation
- bacterial pneumonia/other pneumonia, shortness of breath
- surges of severe headaches, migraines, dizziness, etc.
- fainting collapses by symptoms-mimicking aerosols
- severe stomach pains (sharp, burning, nausea, etc)
- chest-wall pains, heart-muscle inflammations/trauma, etc.
WORSE:
- heart attacks under cover of second-hand smocking
- car crashes/accidents by Vertigo-causing aerosols
- liver/organ failure by small-dose toxins (trace-less?)
- cancer-causing/facilitating - months-long assasinations
This "Yushchenko syndrom" CAN destabilize NATIONs
Waste, Fraud, Cronism and Abuse in HomeSec/FBI
Fabrication of Believable Info/Manufacturing of accidents

U.S. mail IS polluted in "anthrax-like" manner to HARM critics
Libraries, airplanes, hotels, offices, buses, trains - all polluted!

A network of Secret Gas-Aerosol Rooms operated in US
(in Philadelphia, Narberth, Lower Merion, PA)
(in Wilmington and Newark, DE)
(in Hampton, Williamsburg and Richmond, VA)
AND ELSEWHERE.... details below...
Bio-aerosols used to hurt and simulate panic attacks, etc.!
Soviets locked critics into nut-houses, now WE do the same!
Symptoms-mimicking aerosols do HARM, weak or ill people.

Say "Stop, I care" - call Senate (202) 224-3121
House of Representatives (202) 225-3121
What IS going on in America? *Print and
Post*
Manufacturing of FEAR to grab more Power and Money, of course.

Big Brother spins protection...
And fear is used to clamp.
Democracy needs action!
On which side do you stand?

Looked at this?!! Go to Google/Yahoo newsGroups:

TORTURE IN USA: Secret Aerosol Rooms

US Scientist needs legal help dealing with the secret aerosols rooms
(SARs) operated illegally in Philadelphia area, Newark (DE), Hampton
and Williamsburg (VA) and other places. Highly volatile aerosols with
and without bacterial content cause dry cough, airways a...

Full text was at:
http://buyit.philly.com/findit/search/results.jsp?catId=krd_philenqda...

This was a new on-line ad placed in Philadelphia Inquirer and
Philadelphia Daily News on www.philly.com (see full text below)
It was about the secret aerosols rooms in US. One could find it by
searching "secret", say, in the ad section of philly.com.

Democracy can not function effectively without the informed public. As
a former NASA Langley scientist working in the area of nanotechnology
and nanoscale particles, I have been recently exposed to the
establishment of secret gas-aerosol rooms inside of United States, at
least in the Mid-Atlantic region (from Philadelphia to Virginia).
First, the highly irritant aerosols have surfaced at the NASA Langley
Research Center in several safety accidents. Investigations were
blocked, probably, because of lack of Congressional approval for such
financially-lucrative research at NASA. Later, these aerosols had been
encountered outside of NASA in Virginia, Delaware and Pennsylvania
.
This points out to yet another proliferation of originally-sensitive
technologies into domestic American life to hurt and harass people
without a proper oversight and much control. This amounts to torture,
extra-judicial prosecution and authoritarian intimidation tactics. The
use of such irritants and the operations of the secret gas-aerosol
rooms are gross violations of human and constitutional rights of
American citizens and various domestic and international laws.

----------Full text of an ad from Philadelphia's
philly.com----------
TORTURE IN USA: Secret Aerosol Rooms
US Scientist needs legal help dealing with the secret aerosols rooms
(SARs) operated illegally in Philadelphia area, Newark (DE), Hampton
and Williamsburg (VA). Highly volatile aerosols with and without

bacterial content cause dry cough, airways and eyes irritation, chest pain and inflammation. FBI and Homeland Security associates are likely operators of SARs, while collaborators may be hotel staff and landlords, who get financial/material or other incentives. US citizens and kids are victims.

Torture is any act by which severe pain, whether physical or psychological, is intentionally inflicted on a person as a means of intimidation, deterrence, revenge, punishment, sadism, or information gathering. At times, medicine and medical practitioners have been drawn into the ranks of torturers, either to judge what victims can endure, to apply treatments which will enhance torture, or as torturers in their own right. http://en.wikipedia.org/wiki/Torture

America in Danger!

America in danger -
The vice is NOT impeached.
America in danger -
The public trust is breached.

Big Brother spins protection
And fear is used to clamp.
Democracy needs action!
On which side do you stand?

Which side are you on, boys?
Which side moves you on?
Which side are you on, girls?
Which side did you wrong?
(Chorus after F. Reece)

Your church is burned by haters.
The priests to go to jail?
Your dreams are cheyned by traitors,
But hope still shines through veil.

Dust rooms came back to gas us
With neo-Naz (or Con) embrace...
New immigrants do make US!
And not the SSuper-race...

***

The Government of Torture

Our government needs TORTURE?!
It has your VOTE, and, now, support?
But peace (not vice) needs steady nurture
And trustful words of calm rapport.

Beware of loud, but FALSE, ideas
That flame a thirsty hellish torch.

Protect the old and true ideals
And Constitution's civic urge.

Yes, torture IS a hellish torch -
In bloody hands, a blinded sword,
With Constitution used to forge
All laws on rights as mere absurd!

Remember victim's silent cry
And SEE the Christ in all of us.
Don't let your government to spy
And torture with some bio-dust.

There is NO good use for evil torture!
No matter how the need is spinned
By Nixon's men, as bloody sergeants,
While truth is painfully re-skinned.

Group:

I'm truly sorry to hear of Reg's passing.

Although I had never met Reg, I had many interactions with him on this USENET NG and I followed his many postings over the years with great interest.

Reg was that rare commodity among men, a unique individual, "an independent thinker"!

Reg was a consumate technical professional, he knew his business from fundamental principles, and he could solve complex problems using only elementary principles, he had no real need for reference books, handbooks, cookbook recipies, or old wives tales.

He questioned everything and thought for himself.

Like his hero "Oliver Heaviside" Reg Edwards understood Maxwell's four partial differential equations better than Maxwell himself. [Aside: Maxwell didn't know his theory could be captured in just 4 partial differential equations, he wrote them down as 22 separate equations! It took independent thinker Oliver Heaviside to "simplify" those contorted equations of Maxwell into 4 simpler relations.]

Reg was that kind of guy!

Reg instinctively knew that attempting to exactly solving those four Maxwell/Heaviside partial differential equations for practical applications was often impractical for most problems without recourse to heavyweight [sledgehammer] methods of integrating partial differential equations such as used in the multi-million dollar developments represented by the celebrated NEC [Numerical Electromagnetic Codes] such as Method of Moments and/or Finite Element Analysis.

Reg did not resort to "opening walnuts with sledgehammers", instead... using his vast insight into electromagnetic phenomena [If I was an electric charge, what would I be doing now?] Reg found and invoked, often very accurate, and always elegant and simple approximations, I like to call them "nutcracker" methods, rather than "sledgehammer" methods, to solve practical electromagnetic problems.

Reg programmed his "nutcracker" solutions and shared those programs with the world. Free!

Reg often used his "nutcracker" solutions to check the results of the "sledgehammer" solutions which are so prone to misuse by the uninitiated! In fact just before his death I was following USENET

rec.radio.amateur.antenna threads where Reg was "guiding" the "operator" of an NEC program to the "right" answer. The NeC "operator" was coming up with incorrect answers that Reg "knew" were wrong.

When challenged about his methods by mathematicians Oliver Heaviside is said to have replied, "I know my methods are correct because they give the correct answers".

Reg was that kind of man!

Not just a technician he was a teacher and a great human being, he entertained as he taught. A great humanitarian. I will miss Reg and his always entertaining USENET posts.

Tonight I will raise a glass of one of his favorites... Rivaner and my toast will be, "Long Live the TLI!".

Adieu Reg...

With this posting I send condolences to his family, Jean and Peter, I hope you both know that your Dad was "special".

> Can an antenna ever be regarded as a transducer that transforms a radio
> wave
> from 50 ohms to 377 ohms i.e. provides an impedance transformation? With a
[snip]

The answer is a "considered" yes!

Although the [so-called] term "characteristic impedance", often labelled as Zo, and units of Ohms are often used to describe a certain characteristic of a propagation media in field theory, that governs the ratio of the E to H fields propagating in the media. This "characteristic impedance Zo" is not the same thing as "driving point or feed point impedance Z" in circuit theory. Although closely related, circuit theoretic concepts and field theoretic concepts are different views of electromagnetic phenomena.

Characteristic impedance Zo and the units of Ohms are often used as the "name" for the square root of the ratio of mu the magnetic permeability is [u = 1.257E-7 for free space] to epsilon the electric permittivity of a propagating media [e = 8.85E-12 for free space]

Maxwell's celebrated equations then result in the fact that...

Zo = E/H = sqrt[u/e] = sqrt[(1.257E-7)/(8.85E-12)] = 376.7 Ohms ~ 120pi Ohms

This Zo is not the same as a "feedpoint impedance" Z which is the ratio of voltage V to current I.

Z = V/I Ohms.

That said it should be recognized that any radiating antenna is "immersed" in a propagating media, usually free space, and the u and e of that media do have an important affect on the "characteristic impedance, or surge impedance" of the antenna which will in turn affect the driving point or feedpoint impedance of the antenna.

For instance it is well known that the resonant feedpoint impedance (Ratio of V to I) at the center of a half wave dipole in free space is 73 Ohms. If that dipole were placed in another medium other than free space with correspondingly different u and e, the driving point impedance of the dipole

would definitely be affected. So would it's resonant frequency, etc...

And so in that sense, an antenna may be considered to be a transducer and not a transformer. Antennas may then be viewed as transducers that transduce the circuit theoretic variables of electric currents and voltages flowing in and between conductors into field theoretic variables of electric and magnetic fields flowing through a propagation media. And... indeed there is a "reaction" between the u and e of the media in which the antenna is immersed and the currents and voltages flowing in and on the antenna.

The 73 Ohm driving point impedance of a free space half wave resonant dipole [in the ideal case this is the radiation resistance] is a direct result of the u and e of the free space in which the antenna is immersed.

If all other things were held constant and the values of u and e of the medial were changed [i.e. move the antenna from free space where u/e=377 to be under water where u/e=x??? the driving point impedance of the antenna would most certainly change!

[snip]
> long tapered antenna, the feedpoint is at 50 ohms. Is the end of the
> antenna
> at 377 ohms to launch the wave easily into free space? In this case,
> antenna
> is a travelling wave antenna e.g. broad bandwidth biconical. Does the
> impedance gradually change from 50 ohms to 377 ohms over the length of the
> antenna?
[snip]

No! Not really.

Surprisingly, the actual surge or characteristic impedance Zo of a single wire antenna in free space, considered as a one wire transmission line placed high over a ground plane [the earth] is actually in the neighbourhood of several hundred Ohms... say 600Ohms or so.

The exact value of Zo is easily calculated by well known transmission line formulas, that assume TEM mode propagation on the line, and this Zo basically depends upon the height over ground and the diameter of the wire. This is not a driving point impedance but is a "surge impedance". The driving point impedance of the single wire transmission line depends upon where and at what frequency it is "driven" by a source.

Of course because this single wire is quite distant from it's return path [ground] this single wire transmission line is "leaky". That is it radiates and loses, or dissipates, power to some extent, as opposed to what it might do if it were placed very close to the ground where there was a nearby field "cancelling" current flow. [a microstrip transmission line for instance].

We know that if this single wire transmission line high above the earth is driven by a source it will exhibit a driving point impedance that depends upon its length relative to the wavelength of the driving voltage or current. [73 Ohms resistive if it is a 1/2 wave, some other in general

complex Z if it is not 1/2 wave.

[snip]
> The impedance of the end of an antenna (open circuit), where it is a high
> voltage point, is usually 5K or 10K ohms.
[snip]

I believe that you are referring to the driving point impedance of an end fed half wave dipole which is certainly high and in that neighbourhood. This is not a characteristic or a surge impedance.

And so in summary...

An antenna may be thought of as a transducer between a circuit theoretic electro-magnetic venue and wave propagation in a propagating media, but the relationship between the circuit driving point impedance and the characteristic impedance of the media is quite complex and is certainly not a simple linear relationship such as found in a transformer or other device.

As far as I understand there is no practical application that has ever required anyone to quantitatively determine the exact relationship between the Zo of a propagating media and the driving point impedance Z of an antenna that is immersed in that media.

In my opinion such a determination would be a very difficult experimental/engineering exercise. The experimenal problem is one of how does one vary the Zo of a media while measuring the effect on the Z at the driving point? Here's a thought experiment...

Immerse an antenna in a liquid media with a given u and e in an anechoic tank then drive the antenna with a generator while measuring the driving point impedance (V and I) and then pour or mix in some other liquid with different u and e and observe the change in Z.

Would that work?

It could also be accomplished numerically on a computer by using a program [like the NEC programs] based on solving Maxwell's partial differential equations iteratively.

As far as I know no one has ever attempted to do this... and notwithstanding the possibility for "invention" or "discovery" I might ask, why would one want to do this?

Hey it might make a good Ph.D. or M.Sc. thesis... but what is the practical application?

For all practical purposes, the characteristic impedance of the media in which antennas are immersed never changes!

Who cares how Z varies when Zo varies?

Thoughts, comments?

It would be one of the easiest degrees ever attained. NEC-4 allows setting the primary medium to any (reasonable) value of conductivity and permittivity, so you can have the answer in seconds with a free space analysis. Alternatively, you can bury the antenna deep in NEC-4's ground medium and define the ground characteristics for your test.

I did a short consulting job a while back for some people interested in transmitting RF for short distances under water. Immersing the antenna eliminates the substantial signal loss incurred by reflection at the air-water interface when the antenna is out of the water. And antenna system design requires knowledge of the antenna feedpoint Z. I've seen numerous papers in the IEEE publications about antennas immersed in other media such as a plasma, and know that antennas buried in the ground are used. So it's of considerable practical interest.

I suggested something similar many years ago - that the Morse
code exam be folded into the written exam and one score obtained.
I think I suggested that the Morse code exam be 20% of the score.
Others wanted the Morse code exam to be 80% of the score.

The j-pole won't give you much gain. It yields the standard "donut" pattern of a single vertical element. The gain is about 2 dB over a theoretical isotropic (point source) antenna. You lose power in the up and down direction and get an increase toward the horizon.

Whatever you finally decide to use, if you can put it up high, that will improve its performance. If you do the wires-on-a-stick design, make it on one end of a long stick (8 -10 ft) and lean it up against a building or fence. It should be better that that rubber duck!

I have built about two dozen j-poles, all of copper pipe , and I really like them.

>
> Roy Lewallen, W7EL
[snip]

Well thanks for that input Roy, that's very interesting and of course a
useful application.

But for the "thesis" idea I was thinking of something a little more
"challenging", e.g.

Clearly the antenna "driving point impedance" Z = R +jX is a complex
function f (Zo) of the "characteristic impedance" Zo, where in general Zo =
Ro +j Xo = sqrt[u/e] of the medium in which the antenna is immersed.

Clearly this function f(Zo) is the "transducer" function that David [The OP]
was seeking.

It's clear of course that f(zo) will also be a function of complex frequency p = s + jw.

Now expressing this functionality as:

Z(p, Zo) = f (p, Zo)

One might ask [the thesis candidate, (grin)] to derive/discover and tell us...

What. precisely, is the functional form of this complex "transducer" function f that takes Zo to Z [377 Ohms to 73 Ohms! (grin)]

Is f(Zo) a simple linear function? [e.g. like a transformer turns ratio as the OP David had asked] or perhaps... A non-linear function? or maybe... A differential or integral relationship?

What?

Except for a few isolated niche applications, such as those you mentioned having consulted on, I can't really think of any practical applications that demand knowledge of the functional form of "f".

Which is likely why this subject is not mentioned in antenna textbooks or widely discussed. i.e. No one ever needed to know it and so no one worked out this relationship or even investigated it... Simply a matter of supply and demand (grin)! We have Ohm's Law and other such well known relationships such as V = IR because there was a demand by "scienticulists" (grin) to know these relationships to do real Engineering, i.e. build stuff they needed out of stuff they could get.

The discovery of the functional form "f" of this relationship might perhaps be at least suitably hard for a Master's Thesis, a good challenge, and I believe that it is suitably "academic", since there is very little use for it (grin).

What exactly is "f (Zo)"?

Thoughts, comments.

Code is dead - along with anything else that requires skill, practice, or
a little bit of effort.

The folks who want to do away with code should at least learn it and
try it - they might find it to be (gasp) enjoyable. Personally, I could
support doing away with no-code licensing altogether. I realize it won't
happen, but I gotta think that if I managed to learn Morse code, then so
can "they". The only thing no-code licensing accomplished in this neck of
the woods was to move the CB mentality from 11 to 2 meters.

Peter, I for one, have missed your style.

Consider the following:

```
I(s)
+-->-----------------------------------------open
|
V(s) 1/4 wavelength, Z0=600 ohms
|
+--<-----------------------------------------open
```

Given: The ratio of V(s)/I(s) is 50+j0 ohms. Can you
solve for f(Z0)?

learn to use a buggy whip to good effect on and horseless carage
Idon't think so I felt like taking a whip to mine the last time it ran
out of gas nothing would happened Buggy whip are abolslutely useless
wth horseless carrages expect I supose to get better service at the
gas station

Can I ask who uses what in the mobile antenna stakes.

To help narrow it down abit my car is a small one. a peugeot 206 sw / estate.

Have just bought an HF radio for it and looking to find the "right" antenna.

Looking for opinions. I'm edging towards a little tarheel 2 but that means getting it shipped to the uk.

the 20 meter monoband that i bought looks a bit on the long side.

Any advice?

Alan

We could probably modify vehicles to respond to
lashes from a buggy whip and eliminate the
accelerator.

No, but it darned sure wouldn't hurt to make sure they could drive
something with a standard transmission. Never know when the ol'
grind-o-crunch automatic is gonna give out and ya has to use
something more reliable.

3994. MAXWELL's EQUATIONS OF THE ELECTROMAGNETIC FIELD!!!!!!!!!!!!!!!!!! !!!!!!!!!!!!!!!!!!

remaining formulae, which mainly are got by vectorially
manipulating the base equation (30). (44c) is achived by taking
the time derivative of this equation, the (44d) is got by
taking the space derivative of it.

(45) ================================

```
_ _
_ E x v
B = ----2-- (from 30)
c

_ _
_ E x v
DB/Dt = D/Dt ( ----2---- ) =
c

__ _ 2 _ _ 2 2 __ _
!/ v/ c.(E x v ) = -v /c .( !/ x E )

__ _
For v=c DB/Dt = - !/ X E
```

(46) ==

```
__ _ __ _ _ 2
!/ x B = !/ x ( E x v/c )

__ _ _ __ _ _ __ _ _ __ _
!/ x B = DE/Dt - v( !/.E ) - (E. !/).v + E( !/.v )

!------------/ !---------------------------------/
Result Will be zero for a non accelerating
according to point source
Maxwell

__ _ _
!/ x B = DE/Dt The result in accord with
Maxwell valid for a non
accelerating point source
```

==

LIGHT AND ELECTROMAGNETIC WAVES

Beside these famous equations treated above, historically Macwell
is famous for predicting electromagnetic fields propagating in
in the same way as light in free space. The conclusions were made
on basis of comparing results from the general wave equation based
on how sound in air or mechanical waves were propagating in a medium,
air and water for instance. But the modern physics do not confess
any existence of a light bearing aether, and the contradictionary
problem in Maxwell's theories therefore still remain.

Vectorial manipulations are performed on results from (45) and (47)
as shown in below.

(48) ==

__ _ _
!/ x E = -DB/Dt (from 45)

__ _ 2 _
!/ x B = 1/c . D/Dt .E (from 47)

__ __ _ __2 _ __ __ _ __2 _
!/ x (!/ x E) ? - !/ E + !/(!/ E) = - !/ E

__ _
(!/ E is equal to zero for a point source)

__ __ _ __ _ __ _
!/ x (!/ x E) = - !/(DB/Dt) = - D/Dt(!/ x B) =

2 _ 2 2 2 _
D/Dt(1/c.D/Dt.E) = 1/c .D /Dt .E

__ _ 2 2 2 _
- !/ E = 1/c . D /Dt .E

(49) ==

__ _ _
!/ x E = DB/Dt (from 45)

__ _ 2 _
!/ x B = 1/c .D/Dt.E (from 47)

__ __ _ __2 _ __ __ _ __2 _
!/x(!/ x B) = - !/ B + !/(!/ B) = - !/ B

__ _
(!/ B is zero for a point source =

__ __ _ __ 2 _
!/ x (!/ x B) = !/(1/c. D/Dt.E) =

2 __ _ 2 2 2 _
1/c .D/Dt(!/ x E) = 1/c . D /Dt .B

__2 _ 2 2 2 _
- !/ B = 1/c . D /Dt .B

==

The general wave equation is written :

(50) ============================

__2 2 2 2
!/ Y = 1/v . D /Dt . Y

================================

The mathematical structure of (48),(49) and (50) is the same
and it was this mathematical equivalency which gave Maxwell
the idea of light being a medium carried wave. Since then many
experiments have been perfomed by light, clearly showing that
no active light aether do exist. Only the mathematical
equivalency reamin intact.

I took the code test (novice 5WPM) back in 73 in high school, and had the totally worthless (to me) Novice ticket for 2 years or whatever it was. I spent a lot of time practicing CW, back then and also about 10 years ago, and can't seem to get past 7-8WPM, so I gave up on it, the sound of it annoys me anyway. It wasn't worth the stress it caused me to work HF. of course, since I DID pass the 5WPM test, I can be a general now. But, the interest has passed. I have a 2M mobile and an HT, but if I buy an HF rig, it's going to be to listen, but not to other hams, that's as boring as it gets. If I want to hear about hip replacements, and stuff like that, I can visit the folks at the assisted living place my mom's in.

I don't care about HF anymore, the code requirement outlasted my interest in HF. I wanted to be on HF from the time I was a little kid to about age 40 or so. No longer. I have my other hobbies now, guns, PCs, home theater, and dogs. Not much time or budget left for ham radio.

Just because you and I were forced to learn it does it mean a new ham should. It's an obsolete mode in most respects, handy in a certain type of emergency, but of little other use, except communicating with other

people using it. Nobody's stopping them. Nobody should have to learn it either.

But it's funny, the people I hear, both on HF and 2M and 440 causing all the real problems are people who didn't get a no code license, supposedly don't have a "CB mentality", yet do many of the things you can hear on 11 meters all the time, keying up on top of other hams, harassing hams, ignoring calls, etc, based on their call sign timeframe (Thinking if the ham was ticketed after xx-xx-1990 or whatever, they are a "hamster", etc). Seems like the code makes you this way, or maybe getting old does.

I would gladly take the "CB mentality" over the stuff the so-called "good hams" pull.

ALL radio operators are "appliance operators" as you so idiotically
put it. A radio is a radio, no matter who turns the switch on. Does
the range in your kitchen stop being a range if Martha Stewart
operates it?

"Appliance Operator" is a term to distinguish from those who are able not
only to turn on and operate their equipment, but also understand how it
functions and can reproduce the circuitry therein. An appliance operator
knows little or nothing about how the equipment they use works, only how to
```

use it (not necessarily in a proper or legal manner).

Does this mean that only a fully qualified journeyman auto technician
really knows how to drive a car properly?

Does an executive chef at a 5 star restaurant need to know Ohms Law in
order to cook properly on an electric stovetop? Does he also need to
be a petro-chemist to operate a gas range?

The notion that only a person who knows the inner workings of a device
can operate it properly is downright insulting and worthy of utter
contempt.

Can you rebuild the transmission in your car in your back yard right
now? If not then you are a bad driver, according to the "appliance
operator" logic being spewed here.

Unfortunately in the Celwave and Andrew catalog there is a large gap from
5.8 GHz to 24 GHz for sectorized antennas.

Any other ideas?

Hi Alan,

Sure. So's the signal (a compromise). When you get into fractional wavelength sizes (and we're talking on the order of less than 5% of wavelength), you quickly get into fractional performance. It has to do with the comparison of the radiation resistance which at 5% is 2 Ohms. This is 25:1 mismatch, and the matching components are going to have to present less than 2 Ohms in themselves (not forgetting all the connections that support the circulating currents) just to limit your loss to 3dB.

If it were easy, few shootout contestants would be running 10dB below the winners.

Still and all, even if your 100W signal ends up radiating 10W, lots of folks have worked the world with less.

A center-loaded antenna will usually do best.
If you don't use a screwdriver or bug catcher, try a Hustler with the big
coil.
For lower bands the feed point impedance at resonance will be quite a bit
less than 50 ohms, so some impedance-matching scheme is in order.
The worst thing you can do is a whip and a tuner.

Richard,

May I expand on a couple of your points.

Amateurs are very focused on VSWR.

Additionally, they hate narrowband mobile antennas.

Radiation resistance of short verticals on low HF bands is very low,
whether or not they are base loaded, centre loaded, top loaded,
capacitively loaded, or continuously loaded.

Even when the resistance of the radiating car body and earth coupling
are added in, the direct base impedance of a short loaded resonated
vertical mounted on a car is well below 50 ohms.

If the loading coil is made sufficiently lossy, then the feedpoint
resistance can be raised sufficiently to satisfy a "reasonable" VSWR
spec, in fact the better (lower) the VSWR spec for direct feeding, the
lossier the loading coil need to be.

The upside of this is that the bandwidth is expanded, isn't that good!

We have delivered on the two most important criteria!

Well, these things (simplified feed arrangement for tolerable VSWR,
better bandwidth) are obtained at the expense of efficiency.

If you view the world through an VSWR meter, you will be pleased with short direct fed verticals for cars.

If you want efficiency, then it will almost certainly require a base matching network.

With a suitable base matching network and low loss loading coils, you may still achieve reasonable efficiency in a shorter vertical, though low loss coils are not low profile! Secondly, commercial manufacturers of low loss verticals skip straight to long antennas.

Like Richard, I am sure lots of people will be happy that anything "works".

Owen

Would you have 1000 people learn to drive a standard
transmission even though only one person out of those
1000 people benefits from it? The cost/benefit ratio
is extremely high.

(I'll go ya one better - make EVERYBODY drive a standard - or a Harley -
and save some oil. Outlaw automatics!)

Ok then - same goes for satellite communications, fast/slow scan
television, packet, EME, and so on. Lots of applicants will never
use those modes, but the questions are on the test, so you
better learn the material.

K2FRD (I think) proposed what I thought was the best solution to
the Morse code issue - keep it as part of the test, but don't
keep it as a show-stopper. I think it would be fair, at least for
the higher grade licenses, to throw it in there with all the other
modes you may never use.... have it on the test, let the applicant
earn some points from it if they can, but don't send 'em home
disappointed if they don't.

Someone skilled in driving a vehicle with a manual transmission and actually using it can reap a number of performance benefits. These include improved gas mileage, better passing performance, better performance in hilly terrain, etc. If people were required to learn how to drive vehicles with manual transmissions, more of them might actually choose to drive such vehicles.

Riding a bicycle has even more benefits so force everyone
to pass a bicycle riding exam.

The black dot tells you the phasing between the windings; which end you
need to hook where in order to avoid a 180 degree phase shift. If you
look at the primary and secondary voltages on the dotted end of each
winding with respect to the undotted end, they'll be in phase.

Hi Dan, John,

Additionally, the dot is also called the "polarity." That is, when
the input phase is going positive on the primary dotted end of
transformer, all other windings' dotted ends are also going positive.
Yes, this is the same thing as saying their in phase, but when you
look at a schematic it is sometimes easier to think in terms of
polarity, especially when you are looking at ring demodulators.

It's a phase reference for an AC signal. Otherwise,
there would be the possibility of a surprise
phase reversal through the transformer.

Cecil, bicycles (and most motorcycles) need smooth
roadways; it is hard to operate "CW" while mobile and
off-road on a bike.

Now HORSEBACK mobile is the same on-road or off-road. No
gasoline or oil needed nor "gear shifting." Horses can
make "new models" all by themselves, keep themselves
"powered up" without the aid of stations like Exxon, 76,
Shell, or Sinclair. The US Army even had a 'horse
mobile' radio set (1943) to talk while the troop was on the
move. :-)

Everybody ought to learn to "sit" a horse and guide it. :-)

Dee seems to have little experience in long-haul driving,
or even short-haul automotive transport. I learned to
drive in a '39 Ford sedan. The first three autos I owned
were manual trans, a Plymouth two-door (came out west in
it), a '53 Austin-Healey roadster (manual trans went
kaput while downshifting on a freeway off-ramp back in
'60), and a Brit very compact station wagon. A whole
lotta NONSENSE to do the clutch-gearshift thing on all
those manual transmission vehicles even if it was easy
for me. NO "performance increase" whatsoever of manual
versus automatic.

Buying a new 2005 Chevy Malibu MAXX with its better
engine system computer allowed us to get 32.7 MPG
(based on both fuel tank filling receipts AND the
Driver Information Center display of MPG) for a 1,900

mile round trip up to Washington state and back in July this year. That's without using the Cruise Control (which my wife likes but I don't, driving over 90% of the time). About 2 1/2 MPG better than the Chevy Cavalier wagon for the same distance the year before. MAXX had done almost as good MPG in September last year on a much longer distance to Wisconsin, again doing about 2 1/2 MPG better than the Cavalier over the same route the year before that.

The engine computers keep getting better and better, some even compensating for the bad habits of some drivers using the almost-universal automatic. Why anyone would prefer using a manual or automatic in stop-and-go city traffic can be summed up as RATIONALIZATION or braggadoccio by manual trans owners. Besides, operating "CW" in stop-and-go city traffic will seriously cut down one's morsemanship speed with a manual trans. Unless one has a third hand... :-)

Cell phone coverage is growing, growing, growing. My wife used the cell for all kinds of calls while we were moving in MAXX through several states, even checking her e-mail on AOL! Without any skill at morsemanship whatsoever, she "worked" her sister in WA state from the parking lot of a restaurant in Amana, IA, using the cell phone. :-)

Hmmmm. One out of three Americans has a cell phone now. Yet, Blowcode contends "everyone has to learn" morsemanship to have a backup skill in comms? :-)

You are absolutely right! Why didn't I think of that? One caveat,
however - they'll also have to pass a Morse code test with their
bicycle horn. (I forget now - is this so they can drive a car or
use the microwave oven?) This is too silly.

> from 50 ohms to 377 ohms i.e. provides an impedance transformation?

I'd like to take a somewhat different tack on handling this question.
It is a wave versus photon perspective. It seems to be very easy to
slip into the thought mode where we view radio transmissions as a wave
phenomena in some sort of space media. After all, most of the math we
use for electromagnetic signal propagation work quite well assuming
that. Maxwells math still works wonderfully even today, a century after
Einstien described photons. Maxwell died more than a decade before
Einstien published his seminal papers though.

The real model of the radio operation is for there to be alternating
electrostatic and magnetic fields surounding an antenna when it is
driven by an RF power source. Through some yet poorly understood
physical mechanism, either envolving the acceleration of electrons in
the antenna's conductor or from the alternating E and H fields, photons
are flung off the antenna.

I interpret this to mean that what we call the "near field" around an
antenna is the volume around an antenna where the electrostatic and
magnetic fields are at an energy level significantly above natural
background levels. The "far field" I interpret to mean where RF energy
exists as a photon flux.

To describe an antenna as a transducer is probably correct
symantically. It does convert between electrical energy in the form of
RF current and voltage and photons. This is both for transmitting and
receiving.

The 377 ohm thing though is a function of the releative intensities of
the electrostatic and magnitic fields surrounding an antenna. It is a
constant like pi or e. It is an emperically measured characteristic of
our universe. It does not, however mean that an antenna transforms a
feed impedance to this impedance. It simply tells us what to expect for
when we feed an RF current into an antenna. It is much like knowing
that a 1 foot diameter wheel will travel 3.14159265... feet for every
revolution.

Now, a point worth noting is that while RF current in a conductor
produces photons, photons produce RF current in conductors. That, of
course, is why antennas are able to operate for both receiving and

transmitting. That is also why radio signals bounce. Photons are absorbed by objects such as wires or dirt and RF currents are produced. Those currents, in turn, generate new photons. The conductivity and dielectric constant of the absorbing material determine the amplitude and phasing of the current and thus the primary direction of emission of the new photons.

So... Yes the antenna is a transducer. No, it does not transform 50 ohms into 377 ohms. 377 ohms refers to the eletrostatic and magnentic fields as they exist in the near field of an antenna or conductor. It does not refer to what is going on electrically in the antenna conductors.

Anyway, that's my take on the subject.

Even if spelled correctly [you're, not your] Fred is definitely NOT
saying his thing with civility. :-)

Freddie, Mark was saying that - IN THE BEGINNING - ALL radio
services used morse code...and the first US radio regulating
agency wanted all to show competency in this common mode
so that the agency to communicate with all users. That era has
long since passed into oblivion. Just ain't no other radio services
using manual morse code for communications now.

Hardly "flung off" and even less, "poorly understood."

>I interpret this to mean that what we call the "near field" around an
>antenna is the volume around an antenna where the electrostatic and
>magnetic fields are at an energy level significantly above natural
>background levels.

The background levels of EM fields are predominantly in the
milli-micro-nano Kelvins of temperature. Nearly everything produces
an energy level significantly above that.

>The "far field" I interpret to mean where RF energy
>exists as a photon flux.

Photons don't exist in the near field? A flux is simply the bulk of
them; like one electron flowing, or a trillion, is current.

>The 377 ohm thing though is a function of the releative intensities of
>the electrostatic and magnitic fields surrounding an antenna.

It is a function of permittivity and permeability which exists even if
the fields are not there.

>It is a constant like pi or e.

Unless you happen upon something other than a vacuum.

>It is an emperically measured characteristic of our universe.

It is empirically measured, but that does not create its value.

>Now, a point worth noting is that while RF current in a conductor
>produces photons, photons produce RF current in conductors.

How much current is created by your antenna in sunlight?

>That, of
>course, is why antennas are able to operate for both receiving and
>transmitting. That is also why radio signals bounce. Photons are
>absorbed by objects such as wires or dirt and RF currents are produced.

An 10 meter doublet of 1mm wire is exposed to 5 - 10 W of power. How
much can you capture and bottle due to this production of current in
conductors?

>Those currents, in turn, generate new photons.

Photons are generated on the basis of an electron in an excited state
falling to a lower ground state, not by current flow.

>The conductivity and
>dielectric constant of the absorbing material determine the amplitude
>and phasing of the current and thus the primary direction of emission
>of the new photons.

Photons do not follow any particular channel of radiation, not unless
you have a very large lens (few antennas do).

>So... Yes the antenna is a transducer. No, it does not transform 50

In fact, in the near field of an antenna, there is nothing that
resembles 377 Ohms of Z.

The page at:
http://home.comcast.net/~kb7qhc/antennas/Fields/Dipole/index.htm
dramatically reveals that the near fields fluctuate wildly from 377
Ohms, and I have restricted my analysis to those values falling at
roughly 100 Ohms or 1000 Ohms (the hot spots marking the feed point
region and the tips of the dipole).

Other antenna design's modification of the 377 near field around them
can be observed at:
http://home.comcast.net/~kb7qhc/antennas/Fields/index.htm

Not all of those statements are always true. As fond as I am of manual transmissions, sometimes automatics have the advantage. A hydraulic torque converter with a manually controlled "automatic" transmission is better at drag racing than a manual gearbox under many conditions.

This is less true under road race conditions where the lower torque needed to be handled by the transmission allows the newer style "manual" transmissions to change gears in milliseconds. The secret is 2 transmissions, one for the odd gears, one for the even, and 2 clutches, you are literally in 2 gears at the same time for a short period of time. Takes a lot of computer control. That's one way to do it, there are others.

The landscape is very blurred nowadays concerning what is a manual and what is an automatic transmission, with "manuals" in modern race cars being more automatic than "automatics" in non-race cars.

And the state of CW vs digital is about the same. Except CW can always be beat if your PC works. You just need to select the correct mode.

That last statement is a fallacy. The digital modes are wiped out by conditions that will still permit CW to be used. Even SSB can sometimes be used when conditions wipe out the digital. I have repeatedly said and now I am emphasizing: EVERY MODE HAS ITS UNIQUE ADVANTAGES AND UNIQUE DISADVANTAGES. It seems that people wish to deny that whatever mode they don't want to deal with has any advantages whatsoever. They also wish to attribute magic properties to whatever is their favorite mode. Both points of view are foolish.

Name them. I've not found any one mode that can handle all conditions of distortion. However, I have found from time to time that distortion can be severe enough at times to wipe out all digital modes even if you try to switch from mode to mode. Occasionally it can wipe out CW.

I repeat: EVERY MODE HAS ITS ADVANTAGES AND DISADVANTAGES. To deny that is foolish.

I know very little about ham radio and have a simple question about antennas. I have been given some radios that were connected to large roof-mount antennas. I don't seem to be able to pick up anything on them using the standard rubber ducky antennas that came with the radios. I occured to me that the previous owner may have tuned the radios to use the big antennas and maybe that is why the don't work with the small antennas. Is that a likely explaination? Thanks in advance, Twiddler

Everyone keeps ignoring that I maintain that: EVERY MODE HAS ITS ADVANTAGES AND DISADVANTAGES. I keep repeating this but no one cares to acknowledge such a plain and simple fact. Why is that? Are you all so set on bashing what you don't like? Are you all so set on trying to prove that your favorite mode, whatever it may be, is the best?

Unless Pactor II has recently been put into the public domain, it requires buying proprietary hardware to run it instead of using a simple inexpensive sound card interface with commonly available software. Most hams are not thrilled with the idea of proprietary hardware and data modes.

> conductors.
> . . .

377 ohms does not describe the E and H fields in the near field. 377 ohms is the ratio of E to H in the *far field* when the medium is free space or, for practical purposes, air. In the near field, the ratio of E to H can be not only far from 377 ohms, but it's commonly also complex (that is, E and H not in time phase). For an illustration, model a short dipole or small loop with EZNEC or NEC-2, and use the near field analysis to find E and H at some point close to the antenna (within a fraction of a wavelength). When you divide E by H, you'll get a wide variety of results(*) depending on the type of antenna and the observation point. But as you get farther and farther from *any* antenna, you'll find that the ratio always converges to 377 ohms, purely real (that is, the E and H fields in time phase).

(*) The ratio of E to H is called the "wave impedance". In the far field, and only in the far field, it equals the intrinsic impedance of the medium. And, as Gary and others have said, this shouldn't be confused with the ratio of voltage to current at an antenna feedpoint. They are not at all the same thing, in spite of having the same units of ohms.

I don't think so. Perhaps the front ends of the radios have been damaged by static discharge while connected to the large antennas.

What frequencies are you listening to, HF or VHF/UHF? Some VHF/UHF handheld radios come with a rubber ducky and have HF coverage as a secondary feature. On those, you generally can't hear much on HF with the ducky except maybe strong signals at night.

4066. New odd question

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-11 03:10:52 UTC
From: jawod <jawod@fuse.net>
Message-ID: <42be9$4504d42a$453d9423$15423@FUSE.NET>
Source record: 52804

I'm considering a weekend cabin on the Ohio River.
My question is two fold (and possibly twice dumb)

There is an unused cistern on the property and the property is on the shore of the Ohio River.

Question 1:

If the cistern is filled with salt water, would the near field of a vertical be significantly enhanced? Would it lower the TOA?

Question 2:

Does significant flow in a body of water (in this case, the Ohio River) represent a different dielectric than ground or non-flowing lake water? How would it effect propagation from a vertical or other antenna system?

Thanks!

John

Would someone mind explaining how I would model a Slot antenna ?
I am using EZNEC.

My initial assumption is that I create 4 planes to represent the metal
and leave the appropriate gap to represent the slot ?

I am also not sure how to make the feed point attachment.

Thanks in advance

Regards

David Huisman

Hi David,

Presuming you've accurately modeled both the surfaces, and the slot,
you feed across the narrow middle of the slot. The polarization is at
right angles to the slot.

Hi John,

No.

>Would it lower the TOA?

No.

>Does significant flow in a body of water (in this case, the Ohio River)
>represent a different dielectric than ground or non-flowing lake water?

No.

>How would it effect propagation from a vertical or other antenna system?

A vertical would propagate better, at lower angles, along the length
of the water ("along" being in the straight line from the radiator, to
the water, and across, or along the water on the same extended line).

The water, if you will, acts as a "reflector" because it has a huge Z
mismatch to the air above it (more than 10:1, if I recall) and not
because it has some miraculous conductivity (it doesn't). Salt water
also creates illusions of conductivity. Actually, yes it is better
than an insulator, and adds loss galore in comparison. The inherent
beneficial property is that it has an even higher mismatch to the air
above it which aids reflection at lower angles of vertical
polarization.

Now, the distinction is that in the near field, water and saltwater
are piss-poor (pun intended) conductors. You would be better off in a
desert of dry sand, a very poor conductor. On the flip side, at a
distance (where radiation lobes are developed) water and saltwater are
huge sources of low angle propagation for vertically polarized
radiation.

Moral: transmit from on high a sand dune, out over the ocean (or
lake).

Yes, I agree with that completely Roy. I apologize for simplifying my response so much as to not mention this. I was trying to answer the question at the same level as was asked. I did not mean to offend the more mathematically astute members of this group.

I will stand by my comment that radiation from antennas, no matter how well predicted mathematically, is not well understood at a subatomic level. I personally prefer a model that assumes photons result from electron acceleration (or deceleration or energy level decrease). There are obviously competing models.

Heh, heh...

No of course not, you would need more than just this one
experiment/measurement to determine Zo.

The case you depict is at a "singularity" so to speak and is a "pathalogical
case", because with the 1/4 wave line open at the far end, one sees only a
short circuit with Z = V/I = 0.0 [zero] as the driving point impedance and
one needs more equations than just this one singular situation to solve for
Zo of the line.

In fact though if you "vary" the Zo of the line, you would then see a change
in the driving point impendance Z of the line from zero to another value.

From such a thought experiment one should be able to formulate an expression
for Z(Zo).

Thoughts comments...

Every brand of vehicle has its advantages and disadvantages
but I don't see the government forcing anyone to buy a
Chevrolet. What is wrong with a free market of modes?
Nobody is forcing anyone not to use CW.

I didn't mean to imply that there is a single mode that will handle all
types of distortion, just that there are specific modes available that
handle each type. And somethimes absolutely no digital mode or CW can
get through, but that circumstance happens less often as time goes on,
the exception being CW's cacpbilities aren't changing.

Your shouted statement is correct.

Sorry I wasn't clear. One sees 50 ohms, not a short circuit,
and the Z0 of the line is given at 600 ohms. The line is not
lossless and not even low loss. There is enough resistance
in the stub wire to cause a 50+j0 ohm impedance looking into
the stub. I was just wondering what is the nature of your
f(Z0) function.

Well John, the flow in a body of water would not change the dielectric constant, but the signal arriving in the direction of the water flow would arrive earlier than that arriving in the opposite direction. I'm sure measurements using the inverse doppler principle would show a significant difference in the arrival times, especially if the flow rate at the bottom equals that at the surface.

A caveat to the post above: An important issue concerning the above issue
escaped me during that writing. The inverse doppler principle is thwarted in
Pittsburgh at the point of confluence of the Allegheny and Monongahela Rivers
that spawn the Ohio River, because those two rivers flow in different
directions, causing the measurement device to become confused in the Pittsburgh
area.

Hi Dave,

I've seen you refer to service vs hobby a number of times in this thread. As a noob here, could you explain
this? What do you mean by 'service'? Getting on, talking to others...communicating with others seems more of
a hobby to me.

Can you explain the service aspects of ham radio that you are referring to....can you define for me 'service'
and why amateur radio is a service to you rather than a hobby?

Thanks in advance,

noonespecial

Let me simplify the highly detailed explanations you have received...
1. Model the slot as a rectangle/loop antenna of fine gauge wire.
2. Model the outside edges of your antenna as another rectangle/loop antenna.
Fill in the area between the two rectangles that is solid metal with a criss cross of connecting wires.
3. Create a transmission line to feed the two long edges of the slot at mid point...
4. Be aware that Mininec engines are going to be a bit iffy with this kind of structure... But at least you get some ball park figures..

All throughout Title 47 Code of Federal Regulations, the word "service" is used as the type and kind of radio being regulated. It is a regulatory term in that context. One can write the FCC and get that information.

All too often, amateurs who think too much of themselves try to use "service" as equivalent to some (undefined) "national service" such as being a part of the military or a government position. :-)

Part 95 describes Citizens Band Radio SERVICE and the Radio Control Radio SERVICE. :-)

Forgive the top posting

I was requested to define "Amateur Service" ... what service?

"47 CFR 97.3 Definitions:

(a) Definitions of terms used in Part 97 are:

(1) Amateur operator ... redacted
(2) Amateur radio Services ... redacted
(3) Amateur Satellite Service ... redacted
(4) Amateur Service. A radio communication for the purpose of self training, intercommunication and technical investigations carries out by amateurs, that is, duly authorized persons interested in the radio technique solely with a personal aim and without pecuniary interest."

Definitions [a][5] through [a][46] and section [b] in it's entirety have been excluded.

There are three elements of the amateur service: 1) 'self training' in any and all aspects of electro-magnetic radio telecommunication [notice this is listed first]; 2) 'intercommunication' includes talking, satellite techniques, television techniques [yes, amateurs can design and operate wideband tv], microwave techniques, digital techniques, spread spectrum techniques, CW, AM, SSB, FM, etc.; 3) 'technical investigations' include propagation studies at HF, VHF, UHF and microwave, EME activities, antenna developments, new modulation modes [particularly in digital communications], error correction techniques in digital communication, bandwidth compression techniques, and any number of Physics and Electronic areas of investigation.

Amateur [non financially compensated] radio is much more than buying a box and using it to just talk with someone. IMO, it is a service wherein the amateur, a duly authorized person, is committed to self training [education] in some components of the electromagnetic radio communication arts and sciences.

"Duly Authorized" requires authorization by competent authority after a demonstration of some related skill or knowledge by the person seeking to be 'duly authorized'. If a demonstrable skill level is NOT required then "Duly Authorized' does not make sense.

If you just want to talk, the 11 meter band or the FRS will meet your needs.

Another thought: there were a series of antennas,
in the late '60's-early '70's , for vhf (Mainly
2 Meters), called "Skeleton Slots" (think by "J"
beams). These consisted of stacked yagi antennas,
fed by the equivalent of a slot antenna ,Driven el
portions at the narrow's top and bottom, to
each yagi. The (rectangle) fed in the middle at
the narrow center, as you would a traditional slot
antenna .
(I am NOT claiming that this was the most
effecient, just noteing it as it seemed to work
for Stacking yagi pairs).
Might, therefore try a rectangle version of a quad
element, fed at the narrow center. Tho dont know
how much deteriation would be from the slot in an
infinenate field , possible to use as a simplified
model ?? Might give it a try ?? Jim NN7K

I had some good quality RG-213/U lying on the ground for about 25 years. It was moved and flexed quite often. Its loss measures about the same as new coax. However, western Oregon has a very gentle climate compared to most places. Your experience might be quite different if you live in Phoenix or Minnesota, or areas with comparable climates elsewhere in the world.

I have some 20 year old Radio Shack RG-8. I have to assume it was originally of good quality. My assumption is based on the fact that I can't tell any difference between it and new RG-213 bought from Texas Towers within the last couple of years. I did put new connectors on it when I got my license upgrade to General and needed to use it. I also have some new RS RG-8 bought recently when RS was doing a sell off of that part of their stock. It seems to work OK also (especially considering the close out price of $9.95 per 50 foot length). I may have to eventually put new connectors on it since it came with the swaged on PL-259s, but its holding up all right after 2 months of use. Our local weather is rather harsh, mainly strong sunlight, since it appears to have forgotten how to rain here in south central Oklahoma along the Red river.

I would bet Minnesota is even better as long as you keep the water out
during the rainy seasons. We spend more time under 32F, which means
dry, and have less ultraviolet to degrade the jacket.

Of course Phoenix is ideal, except for the UV.

I learned sufficient code to gain my upgrade to General in 2005 and passed the written test the same evening. I have no interest in using code further. I may change my mind on that later, but given my advanced years, the point may be moot. My primary interest as a Ham is in fiddling with antennas, only one of the 11 antennas scattered about my 7 acres was purchased. There are 5 at my detached shop/shack and 6 more back at the house to use when I desire air conditioning while pursuing my hobby. Three of these are indoor dipoles for use when bad weather threatens, as it often does here in southern Oklahoma. I hope all you other gentlemen continue to enjoy the access to the Amateur Bands allowed by what ever license class you possess.

Why not? Picking what you want to use isn't okay? You don't want
alternatives to CW. Or alternatives to digital? Or , for that matter,
alternatives to voice modes.

So for you choice is bad?

Different brands of cars are not dissimilar enough to compare to different types of modes so the analogy doesn't work. The different brands of cars (Chevy, Ford, Chrysler, etc) are more like comparing a Bencher paddle to an MFJ paddle to a Kent paddle, etc. If you use CW, you pick your own type of paddle. If you drive, you pick your own type of car.

> f(Z0) function.
> --
> 73, Cecil http://www.w5dxp.com
[snip]

I like working with Cecil!

Like a Zen Master's rehtorical approach to facilitating understanding, Cecil's approach
to this seemingly paradoxical "circuit-to-wave transducer" question is quite illuminating.

Cecil has neatly sidestepped the fact that, even for the simplest practical antennas, elementary analytic
formulae for antenna driving point impedances have never been discovered. Let alone formulae that explicitly
show Zo as an independent variable.

This [obscure?] fact [of delinquint formulae] often comes as a surprise to most electromagnetic novitiates, I know it did to me.

[Aside: As far as I know, the fact that no one has ever worked out an exact analytic formula for the driving point
impedance of a simple practical half wave dipole, is not a problem in practices since other
approximate and/or "sledge hammer" style numerical methods provide appropriately accurate answers to all
practical Engineering questions about such matters.]

However, as a "seeker of truth", Cecil has noted an easier path as an approach to the apparently paradoxical
question of the relationship of driving point impedance to the wave or characteristic impedance of free space
or any other propagating media.

Cecil has zeroed in on an alternative that might give us some insight!

Namely the relatively simple "exact" formula, first revealed by Heaviside and Kelvin approximately two hundred years ago, the celebrated formula for the driving point impedance Z = V/I of a lossless transmission line of characteristic [surge] impedance Zo
terminated in a load impedance ZL. This driving point impedance is given by the surprising simple relation...

Z(Zo) = Zo[(ZL*cos(theta) + jZo*sin(theta))/(Zo*cos(theta) +
jZL*sin(theta))] (1)

Where theta = 2*pi*(d/lambda) is the relative fractional length of the
transmission line, where d is
the line length and lambda is the wavelength of a sinusoidal signal
supported on the line at the particualr
frequency of interest. Zo of course is the characteristic [surge or wave]
impedance of the line.

It is also well known [Again Kelvin and Heaviside] that Zo can be simply
expressed in terms of the fundamental
transmission line parametric constants [R, L, C, G] by the [equally]
celebrated formula for the characteristic
[surge or wave] impedance of the transmission line as

Zo = sqrt[(R + jwL)/(G + jwC)]; Where, in the lossless case R=G=0.0, Zo ->
sqrt(L/C).

[Aside: The terms Impedance, and Reactance were first defined by (Reg
Edward's hero) Oliver Heaviside. I wonder
if an equally simple formula for the driving point impedance in terms of the
Zo of free space for some simple
antenna is lying out there somewhere waiting to be discovered (grin).]

As can readily be seen, the driving point impedance Z is a function of the
dependent variable Zo and...

although the effect of this relationship is often referred to as an
trasmission line impedance "transformer", the analogy
between the so-called "transmission line transformer" (or should we say
"transducer") described by (1) falls short of
the simple turns ratio relationship where Z = ZL*N^2.

To gain insight here, Cecil has obliquely suggested that, instead of
searching for an antenna formula, that we invert
the celebrated formula (1) and use it to determine unknown characteristic
impedance Zo by assuming ZL known, and
measuring Z.

Inverting formula (1) we obtain the following relationship.

Zo(Z) = ZL[(cos(theta) - jZ*sin(theta))/(Zcos(theta) - jsin(theta))] (2)

[Aside: Apart from the fact that line parameters L,C are also implicit in
the wavelength, Cecil is this right?]

Thus we see that the relationship between Zo and Z is not a simple linear
relationship as for the common transformer,
but instead is, what mathematicians often refer to as, a so-called "bilinear
relationship.

I wonder, is it possible that such a simple relationship exists for some
antennas as well as transmission lines?

An interesting invention... now it will be public domain (smile).

One could clearly construct a sensor to measure unknown Zo's by constructing a small piece of rigid air dielectric
terminated transmission line and then "immersing" the sensor in substances of unknown Zo and then determine those unknown
Zo's by measuring the driving point impedance Z. The calibration curve for this Zo sensor would be the inverse
relationship (2).

Sigh, it's too bad there is not a simple analytical relationship like (1) for antennas, for perhaps this would
address the OP's question of the relationship between 377 Ohms free space wave impedance and 73 Ohms driving point
impedance more directly.

On the other hand we now can see that, contrary to Roy's recent assertion up the thread (grin), that certainly an exact
analytic solution to this problem is likely a challenging Ph.D. thesis topic.

For... after two hundred or more years [As far as I know...] no one has yet worked out an exact simple
analytical expression [similar to (1)] for the driving point impedance of any simple practical antenna.

A Ph.D. thesis indeed!

Thanks Cecil!

I would carry it by hand. It's not worth going to a lot of
trouble for just one bit. Perhaps you could send it using a
flashlight if there is someone at the other end to see it.
Of course if you have do send one bit on a number of occasions
some other means may be required.

The above is intended to show you that more information is
required before we can answer your question. That's my
two bits worth.

Quite a bit depends on your criteria of what is "bad".

All my coax was purchased in the late 1970's and early 1980's for
HF-UHF work. I was very critical of losses at 440 MHz.

I now focus on the HF bands and find the losses acceptable.

All of my problems through the years have been at the connectors.

Even a 'computer science student' should have thought of using a
postcard. Less cost than First Class Mail -- even if "cost is not an
issue." Just write a BIG "1" or "0" for the appropriate 'bit' on the
card and send it off.

Of course, you could always encrypt it -- if necessary.

Then, you might use rifle shots. One equals "bit". Two equal "no-bit".

I suppose "place A" could always telephone "place B", and inform them of
the state of the bit.

Of course, it usually requires more 'bits' to complete a homework
assignment.

What got me going on this subject is months ago, someone asked what would be the feedpoint impedance of an infinitely long dipole in free space. Reg said it would be about 1200 ohms. Since that figure is obviously related directly to Z0, it got me to thinking about the similarity of dipoles to transmission lines. In fact, Balanis, in his 2nd edition "Antenna Theory" illustrates how a dipole is created by gradually opening up 1/4WL of a transmission line. That's on page 18. The current distribution on the dipole after unfolding is the same as the current distribution on the transmission line stub before unfolding.

For transmission line analysis, we begin with simple lossless line formulas and then add complexity such as losses per unit length. For what we call near lossless feedlines, we often ignore the losses or at least consider them to be secondary effects. Going where angels fear to tread, I thought, why can't these same principles be applied to dipole antennas with admittedly reduced accuracy? Or as one of the r.r.a.a gurus said: "A wrong answer is better than no answer at all." :-)

My thoughts didn't go to solving for Z0 as you did above. Using the well known Z0 formula for a single wire transmission line above ground, we get Z0=600 ohms for #14 wire 30 feet above ground and it certainly bears a resemblance to an infinite dipole made of #14 wire 30 feet above ground. Putting a differential balanced source in the middle of the single-wire transmission line would result in a balanced feedpoint Z0 impedance of 1200 ohms. 1/2 of this dipole resembles a 1/4WL stub. An infinite dipole is, of course, a traveling wave antenna.

This is getting long but I think you can see where it is going. Make each 1/2 of the dipole equal to 1/4WL and we have the standard standing wave antenna. Analyze the 1/2 dipole as a lossy 1/4WL stub with a Z0 of 600 ohms not differentiating between radiation loss and other losses. (For this purpose, we are not interested in analyzing the radiation.) Hence, the earlier lossy stub where the impedance looking into the stub was 50 ohms and the Z0 was 600 ohms.

Now quoting Balanis again, page 488 and 489:
"The current and voltage distributions on open-ended wire antennas are *similar* to the standing wave patterns on open-ended transmission lines." "Standing wave antennas, such as the dipole, can be analyzed as traveling wave antennas with waves propagating in opposite directions (forward and backward) and represented by traveling wave currents If and Ib in Figure 10.1(a)."

Figure 10.1(a) is very similar to the graphic depicting a single-wire transmission line over ground where:

Z0 = 138*log(4D/d) D=height, d=wire diameter

Hardline is good stuff, right? Does anyone make their own out of copper water pipe?

Seems doable, but have never heard of anyone doing it.

This is what happens when I have too much time on my hands. :-)

Here in southern Oklahoma enterprising copper thieves are stealing ground wires off power poles and copper tubing from outside air conditioner units, I think their beady little eyes would glow happily at the sight of a hundred and fifty or two hundred feet of DIY copper hardline in someones back yard. Shoot, they'd probably jump the fence flatfooted and fight your family dog for 25 feet of it.

[snip]

Well, as we all "know" the current wave on a dipole antenna is exceedingly close to sinusoidal, but not [exactly] sinusoidal, because if it were exactly sinusoidal it wouldn't be radiating. That [small] difference between the actual current distribution on an antenna and the actual current distribution on a transmission line is the [tell-tale] residual that separates us from an exact analytic expression for the driving point impedance of a dipole.

Interesting stuff...

Our man Reg [Edwards, RIP] always said that... "an antenna is just a lossy transmission line." And of course that is what it looks like approximately.

Heh, heh... everyone always wanted to know the "mathematical" formulae and theory behind Reg's compact programs. He tantalized us all with a peek or two at some selections of his Turbo Pascal source code, but essentially left us all wondering... "How does he do that?"

Apparently, at least one could infer so from his comments, Reg often modeled antennas as "lossy" transmission lines in some of his "nutcracker/lightweight" programs. Did he use the Heaviside/Kelvin formulae? I wonder...

It would be interesting to compare how closely the input impedance of a 1/2 wave lossless feed line of appropriate Zo (Say 600 Ohms?) terminated in a 73 Ohm resistor would approximate that of a "real" dipole. At resonance it would be 73 Ohms at least.

Such a comparison should be simple to check using EZNEC numerical readouts for the dipole and comparing to the numerical results obtained from the formula (1) for the input impedance of the terminated line.

[snip]

In many transmission line modeling programs [such as the ones used by the designers of xDSL modems who, unlike radio amateurs, need models that range from DC and on up over many decades of frequency range.] the fundamental transmission line parameters R, L, C, G are often replaced by [empirically derived] functions of frequency that represent "perturbations" from the constants to mimic skin and proximity effects. Both R and L are simultaneously affected by skin and proximity effects. Of course both Heaviside and Kelvin knew of these effects but could not include them in their simple derivations.

Speaking of the "L" parameter and proximity... I thought the article by Gerrit Barrere KJ7KV in the most recent QEX was interesting because he points out that a large fraction of the "L" parameter in transmission lines results from the mutual inductance between and because of the proximity of the two conductors not the individual self inductance of the conductors.

This is not obvious when looking at the "standard textbook" presentation/derivation of the Heaviside/Kelvin formulation for a differential section of transmission line. Such standard textbook derivations almost universally begin with a lumped differential model consisting of series R, series L, shunt C, shunt G per unit length with no mention of mutual inductance. In fact of course the "standard" model is "equivalent" to a model that explicitly exhibits the mutual inductance, [Because Leq = L1 + L2 + 2M] but it is much more physically satisfying to see the transmission line inductance presented the way Barrere did.

Hi....Im new to ham Radio and have an all-band discone on my roof that I use for my scanner. I also will use this antenna to transmit with my ham radio. So far, it works OK for the transmissions.
Lead in line is 50ft of LMR-400 with 'N' connectors. My question is, Can I split the line for 2 locations? I like to listen to my scanner in my back yard and transmit with the Radio but I also would like to have a line indoors when the weather isnt great. Can I add a splitter and run a new line indoors ?
Or, should I have a dedicated line to run inside? Thank You for any responses....Mike

[snip]

Correct, but don't we all believe that the wave impedance of "free space" is approximately 377 Ohms...

Everywhere...

Even in the near field of an antenna.

That is an antenna itself has no effect on the fundamental u and e of the media in which it is immersed. u and e are defined only in terms of and as affecting "plane wave" [TEM mode?] propagation, and...

After all the antenna is very small, and free space is very large (grin), and so a tiny antenna cannot change u and e everywhere!

The fields E and H in the "near region" of an antenna where the waves are not "plane" on the other hand may not be related by 377 Ohms, simply because the waves emanating from the "near" antenna are not plane, but...

There might just also be plane waves passing through identically the same region of space, say emanating from a more distant antenna. The ratio for those plane E and H fields will indeed be 377 Ohms over the exact same region of space where Zo is different because of simultaneous but non-planar waves.

So in fact... the wave impedance of free space can have many values simultaneously, one [universal?] constant value of ~377 Ohms for plane waves, while it may have many other [arbitrary] values for waves passing through the same region of space that are not plane.

Thoughts, comments?

Yes you can roll your own hard line, Im not sure its worth it though. I had about 100ft of Cu pipe that had been setting around for about 30 years. I would have probably been better off selling the pipe and buying the hardline. After I realisesd I would have to keep it pressurised ti keep out the water I pulled it out and replaced it with LMR 900.

Cecil, I got the antenna up Sunday, for now the stub is straight out from
the antenna. Is it normal for the 50 ohm point to be a little hard to find?
About the best VSWR I can get now is 1.7:1 This is pretty close to the point
where my radio starts limiting power. I m thinking either the stub or the
antenna may be a little long is there an easy way to tell or is easier just
to try something and see what happens? Checking the VSWR at differerent
freqs doesnt help much. Maybe a slight indication that it is too long.

Jimmie

It's possible... there are quite a few standard copper pipe sizes that
come out to 50 ohms.

I think supporting dielectric disks or whatever are the hard part in
rolling your own. We did actually build a small section of 50 ohm
hardline for a sodium droplet pinch-off experiment here... I think it
was 1/2" pipe inside 1 1/2" pipe.

If you were trying to do a long run of it, though, you'd quickly get
into assembly hell. #10 wire inside 1/4" refrigeration tubing comes
out awfully close to 37 ohms; tried to make a matching section for a
440 MHz yagi this way, but I couldn't figure out how to keep it
centered, so it never worked out.

Of course, but for conceptual purposes, both Balanis and
Kraus seem to give us permission to consider the current
distribution to be sinusoidal for "thin-wire" dipoles.
Kraus says: "... it is assumed that the current distribution
is sinusoidal. Current-distribution measurements indicate
that this is a good assumption provided that the antenna is
thin, i.e. when the conductor diameter is less than, say,
lambda/100." Balanis agrees: "If the diameter of each wire
is very small (d << lambda), the ideal standing wave pattern
of the current along the arms of the dipole is sinusoidal
with a null at the end."

Of greater interest might be the construction of a stub using
resistance wire to simulate the "loss" to radiation plus all
the other losses. As one of gurus on r.r.a.a said, "One can
replace the resonant antenna with a dummy load without changing
anything." :-)

At about $25 for ten feet of 3/4" copper pipe, plus lots of time to put it together, why bother? I have made short sections for matching and the like, but wouldn't consider trying to make a long run of it. I do still have some scraps of 1" thick Teflon from when I helped make a quarter-wave length of 22 ohm 6-1/8" flanged line to go from 50 ohms to 10 ohms (five 50-ohm ports in parallel). Wow, that was a long time ago now.

Cheers,
Tom

You've discovered the problem with SWR meters. They
don't read phase. If you were using an antenna analyzer,
the solution would probably be obvious. With only an
SWR meter, your tuning algorithm either converges or
diverges but you may not know which. The easy way to
tune the antenna is to use an antenna analyzer to
determine where the impedance is purely resistive and
then adjust the stub tap point to 50 ohms. An antenna
analyzer is a good investment.

---

50 ohm line is about optimum for power handling, given the ID of the
outer conductor, and 75 ohm line has about the least attenuation for a
given ID of the outer conductor. I think a European compromise was to
choose 60 ohms as a standard impedance.

The research I've done indicates that the old British pipe sizes
(1/2",. 3/4", 1") specified internal dimensions, while the new pipe
sizes use external dimensions and a wall thickness. Did the story take
into account this change in convention?

:-) It shouldn't be vague. It should be crystal-clear. If lowest loss is important and you're going to use coax with smooth conductors and the same metal for inner and outer conductors, and you have a fixed outer conductor diameter, you want the ratio of the inside of the outer conductor to inner conductor diameters to be 3.59:1. That assumes negligible dielectric loss. It's not difficult to find the ratio for other cases, if you know the ratio of RF resistivities of the inner and outer conductors and the dielectric loss. The loss doesn't increase very quickly as you get away from that ratio some, but that's the ratio for lowest loss. If you have air dielectric, that 3.59:1 ratio gives you 76.7 ohms. If you have solid polyethylene dielectric, it gives you about 50.6 ohms. Foam dielectric would give you roughly 60 ohms.

There are different conductor diameter ratios for maximum voltage handling (assuming uniform dielectric breakdown rating and a fixed outer conductor size; you want a conductor diameter ratio that minimizes the maximum voltage gradient, i.e., the gradient next to the center conductor) and maximum power handling (assuming the line is voltage-limited, which generally only is the case for very low duty cycle, like radar pulses). If the line is thermally limited (almost always the case for typical ham installations), lowest attenuation will give you very close to the highest power handling...details depend on how well the center conductor can get rid of heat.

Cheers,
Tom

It would be very difficult to use a simple splitter that would have enough isolation to keep the transmitter's power out of the scanner, if they were both connected at the same time. You need some sort of switch in there. An alternative is to simply use two separate antennas, physically separated by at least a few feet so the receiver doesn't get hit with too much RF power. The separation you need depends on the receiver and the power you're transmitting. Err on the side of "more than enough" separation.

You could make an automatic switch, but making one fast enough and protecting the receiver well enough is a challenge I wouldn't recommend for someone new to this stuff. Better to just connect the antenna to the unit you're using at any one time, if you're only going to have one antenna.

Cheers,
Tom

Hi Peter,

To how many places? Your question is rather oblique when we are
discussing near fields and antenna as "transducer" [not a choice of
term I subscribe to].

I seriously doubt that you've unhinged from the origins of that value,
however, it bears only tangentially on the matter.

Are "thoughts" related to "beliefs?" Bloated speculations of
background radiation don't change the basic assertion that in the near
field, there is nothing that remotely approaches the presumed 377 Ohm
specification. You've both (earlier) acknowledged this and (have
since) challenged it with a semantic fog such as:

>I know that Special Relativity [Maxwell's equations] is not supported in
>full by General Relativity, but surely even though space is warped by mass,
>superposition must still be supported. The radiation in your neighbourhood

OK, ok... you've busted me...

I admit that circuit theory is on really shaky ground.

Although circuit theory was developed by Ohm, Kirchoff and others before Maxwell presented the world with his celebrated equations, we can all agree that circuit theory is a very poor (one dimensional) approximation to field theory. Circuits are a thoroughly useless affair dealing only with poorly understood approximations to the "real deal"...waves!

I admit it, there is no such thing as "voltage", which after all is only the value V of a definite line integral of the vector field that depends upon the somewhat arbitrary path of integration, chosen by the integrator, through the appropriate E field, and so consequently there is no such thing as a "real" driving point impedance Z = V/I. The only reality is the characteristic or wave impedance! There I've said it!

So... youv'e got me... I agree... we should not really be messing about trying to define phoney "transducer" functions between circuit theoretic variables (V, I) and wave theoretic variables (E, H) since the former have such an ephemeral existence.

Still in all... one wonders... do circuits and waves, charge particles (electrons) and waves particles (photons) have any truck with each other or... do they lead entirely separate lives? What would you call the intermediaries between reality and approximation?

I'm very sorry to have brought up the subject... I've probably confused the OP, and I am here and now prepared to recant my heresy, before you light the kindling beneath my feet, heh, heh... I solemly swear that an antenna is not a "transducer" between circuits and waves! (grin)

But... ahem... the sun still has spots!

Kathy, bring me another glass of that Rivaner!

Molly Bloom indeed!

Source record: 52583

When I was experimenting on 440 MHz I made several 1/4 wave matching sections out of 1/2 inch copper pipe. PL259s on the ends with hose clamps on the connectors. By varying the inner conductor it was pretty simply to construct the impedance needed.

The reason for the need was that when you stuff a military surplus cavity to raise the frequency you also booger up (technical term) the impedance of the system. An appropriate quarter wave section would go a long ways toward matching 50 ohm line to antenna.

It would take a lot of motivation to construct your own hardline.

Thanks to all,

for your comments and opinions.
I expected this type of arguments!

Let me comment them:
N3OX, Dan, wrote his confession in antennas...
The fundamentel part :"We believe in the fundemental difficulty of
delivering power efficiently to physically small radiating structures,
and we understand the limitations it places on such structures as
compared to their full-size counterparts."
The difficulty is here, and most antennas of traditional design are
suffering
under this, and therefore are inefficient, if the relation l/lamdba is
small.
That's different in my design:
The Varylink is part of the antenna and permits to feed the available
input power with over 90% efficiency into the radiation resistance Rr
of
the antenna. Furthermore, the relation Rr / Rloss is very high, which
ensures that the power is radiated, and not burned.

Wim, PA3DJS, is addressing a very similar problem.
He calculates an overall efficiency of 5% (-13db) under his
assumptions.
He is also basing his calculation on data available from traditional
constructions. Im my design X/r is between 28 and 50, depending
upon frequency and version, and at the same time the total series
loss resistance is about 10 times smaller than the radiation
resistance.
These characterists ensure, that the efficiency (radiated
power/accepted power)
is in the order of 90 percent.

Cecil, W5DXP, is referring to EZNEC, calculating that the small antenna might
achieve practically the same radiation as 1/4 lambda monopole.
His problem again is, how to get the power into the radiation resistance of
the antenna. This is done as said above.

RF, Richard Fry, is addressing the losses in the matching, and most important,
in the ground loss.
The efficient matching is answered above.
The ground loss is very important for efficient radiation of the energy into
space and not into the ground!
This ground loss is not addressed in the IEEE formula for calculation of antenna
efficiency, as it says: efficency =
radiated-power/antenna-accepted-power.
This does not take care of the fact, that in most real antennas, a large amount
of the radiated power is lost in the ground as induced ground currents!

To minimise these losses I am using a special grounding concept, based on
a differential, floating feeding system, ensuring that ground losses are minimal, and that
the radiated RF energy reaches the space towards the ionosphere.
All this ensures the high efficiency of the small antenna, so far not reached by other designs.

Felix Meyer, HB9ABX

It's Not a Code, no code problem, it's a generational problem!

In the past week, the articles that seemed to get the most play on ham sites were the Southern Border Volunteers and the lack of brotherhood in ham radio.

I was amazed at the responses that were both negative and critical of supporting a group that wanted to protect our borders. I suspect some passengers were probably tsk tsking the only guy in four airplanes with the guts to do something to stop the rag heads on 9/11. How else can you explain rag heads armed ONLY with box cutters were able to control three airplanes? Many of the younger generation find it easier to criticize than take action.

Ham radio went to hell when Dick Bash got involved with his published "cheat sheets".

This piece is from the prospective of a ham with over 50 years spewing RF throughout the world. At 68 years of age, I look back at my start in ham radio, appearing before a steely eyed FCC examiner in Norfolk Virginia. I missed the distance for a Conditional license by about 11 miles. I had to walk between school and home in the snow, uphill both ways.

Do I think that everyone should have to do what I did to become a ham? Nope, I can live with the memorized exams, the no code, etc. Like the parable of the workers in the vineyard, I accept the rules have changed. At no place in the parable does it tell the late arriving workers to ridicule those that worked all day.

Just as sure as these words are on your screen, you too will someday be an old fart just like me. As you enter the dotage of your life, health concerns and the condition of your aged friends, becomes more of a concern. We, like you, used to talk about more contemporary subjects. Unlike a number of you, we allowed the older folks to have their conversations without ridicule. It is called respect, and is a two way street. Realize that when I was a newby, I suffered the same as you at the hands of the old farts. They believed that for you to enter their group, you should first show respect and learn to snatch the pebble from their hand.

None of you started in your working life as the CEO of the company, yet many of today's generation feel that a newly minted license conveys total knowledge. What you have is a license to learn, take advantage of it and the brotherhood will naturally follow.

If we all took the time to show each other respect, and be less quick to judge, not only would ham radio be better, but our lives as well.

Felix,

I call Bullshit. Show us REAL data on the efficiency of this antenna. Show us field strength vs. a full size 1/4 wave vertical with a good ground system. If you've invented something new and innovative, awesome, but the world will never know about it. Why? Because you won't do real tests.

You want people to buy your plans. You make outrageous claims of efficiency with no data to back it up other than signal reports from closeby EU stations on 160m. As far as I'm concerned, at best, you're a optimist blinded by excitement who's built a pretty good low band mobile antenna and doesn't want to let himself down by measuring anything. At worst, you're an outright scammer.

Actually, you know what, how much do you want for the plan again? Maybe we can take up a collection so we can build one and prove that you're wrong. But you know , I bet if we build it and it doesn't work as advertised, you'll make some claim about construction tolerances or sensitivity to nearby objects, or some such and still claim that YOUR antenna is 90% efficient. Such is the way of a good pseudoscientist.

Dan

I think before I start cutting I will try adding a little series capacitance
or inductance to the antenna and see how it reacts to that. My work week
just started so it may be a week or so before I get back at it again.

Dear Cecil:

For us, in Argentina, the 75 ohms 3/4" "free tails" hard lines from CATV installers, are great for VHF & UHF. Imported 50 ohms HL are very expensive, and now RG-213 too (3 U$D/m) (and paymento for our jobs are relative low in international currencies).

I have seen nice "plumbers delight" cheap and simple home made connectors in a website (I try find its URL).

I don't know how many time its dielectric conserves its integrity but I suppose it is more that a RG-8 survives in the atmospheric real sonditions.

I don't believe I've ever encountered the term "wave impedance of free space", and its use is certain to cause confusion, as I sense here.

The *intrinsic* impedance of free space is 377 ohms. The *wave* impedance of an EM wave in that medium is 377 ohms if it's a plane wave in the far field of a radiator, and some other value if it's close to an antenna or other conductor or dielectric. The *intrinsic* impedance of free space is determined only by the conductivity, permittivity, and permeability of the medium; the impedance of a wave is governed not only by the intrinsic impedance of the medium but also other factors.

If you have a reference that defines and uses the term "wave impedance of free space", I'd like to look it up to see how the author deals with this potentially confusing combination of terms. If it does indeed "have many values simultaneously", it's pretty useless in my opinion.

In order to guarantee the ability to obtain a 1:1 SWR, you need to be
able to adjust at least two independent or partially independent things.
This can be two variable lumped components; any two of the following:
stub length, position, and Z0(*); and so forth. Adjusting, say, a stub
length and the value of a capacitor across the input end of the stub
won't do it because they're basically adjusting the same thing and
therefore aren't independent. If you've only been varying one item,
you'll get a perfect match only if lucky.

If you're as close as 1.7:1, it's likely as easy or easier to find the
solution by trial and error rather than calculation.

The reason that two adjustments are required is that 1:1 SWR requires a
particular value of R and a zero value of X. If you vary only one item,
it'll change only R, or only X, or, more likely, both R and X but in
some fixed relationship.

(*) Because you can practically adjust Z0 over only a relatively narrow
range, this is a good method only for fine tuning or as a way to set the
range of other adjustments.

The hijackers on Flight 93 were stopped by more than one guy. And the
people on the other planes did not know the hijackers were on a suicide
mission.

> How else can you explain
> rag heads armed ONLY with box cutters were able to control three airplanes?

Simple:

- The hijackers killed one or two people who tried to resist.
- Then they said they had a bomb aboard.
- They also said that if the passengers did as they were told, nobody
else would get hurt.

You have to remember that before that terrible morning 5 years ago,
suicide-hijacking was unknown. Hijackers took over planes to get
ransom, or to get transportation somewhere, or for political reasons.
They always had demands and always promised that if their demands were
met, nobody would get hurt or killed. And the conventional way of
dealing with them was to do what they wanted, get the plane on the
ground safely, negotiate, and then go after them on the ground.

All that changed on Sept 11, 2001. Look what happened when that
shoe-bomb guy tried it.

The folks on Flight 93 had two things the people on the other flights
did not:

1) They *knew* the rules had changed - they knew what the hijackers
were going to do.

2) They had time to formulate a plan and time to implement it.

> Many of the younger generation find it easier to criticize than take action.

Just like their predecessors.

Well, I don't know if it "went to hell" but I agree 100% that Bash's
"cheat sheets" were a very bad thing for amateur radio.

Remember, though, that it was the top folks at FCC who decided not to
prosecute Bash. Lower-level FCC officials had evidence against him, and
wanted to go after him with criminal charges - but the leadership said
no. Those FCC folks who decided to let Bash get away with his "cheat
sheets" almost 30 years ago were not young people then.

Roy has given you some good advice.

Some further thoughts.

I assume that the coax is not decoupled, that will complicate
achieving your outcome.

Before cutting things, an observation of whether VSWR is better at a
higher or lower frequency will help guide you in the reactance
dimension of the problem.

Find the tap point for lowest VSWR, change frequency and do it again.
This will hint to you whether the antenna / stub combination is short
or long.

Keep in mind that there is not a correct length of the radiator
independently of the stub, small reactance due to the radiator being
off resonance can be compensated by suitable stub dimensions. That
says cut / lengthen the elements that are most convenient.

Temporary increase in length by clamping an additional conductor to
top of the radiator might less final that cutting bits off. Again, the
shift in point of lowest VSWR is a hint.

With knowledge, you should be able do this easy enough without an
antenna analyser.

Owen

Normally you only seal one end of the line. That is to prevent the
line from developing a light vacuum when it gets cold or high
barometric pressure.

[snip]

Delay through a coil... what is that? Heh, heh...

Nickola Tesla would be rolling over in his grave if he could hear us discussing a possible dichotomy between lumped and distributed systems. Nickola "lived" in the intersticies between the wave theoretic and circuit theoretic fabrics of reality.

It is interesting is it not, that the "only" element of circuit theory that allows for "action at a distance" [a.k.a. "field effects"] is that of mutual inductance "M".

Circuit theoretic elements; R, L, C, and M...

Other than "M" circuit/network theoretic concepts are devoid of the wave theoretic aspects of the celebrated Maxwell/Heaviside partial differential equations.

Funny what you can do with "M". Variometers, Tesla coils, and such...

Source record: 52612

I've got a few HF dipoles in our back-yard, and thus far have not used any of these "surge suppressors" and would appreciate a little advice from the NG about such things. I'm reviewing the MFJ-272 but I'm sure there are others similar. Doesn't protect one from a direct hit (I know), so... if we must always disconnect the coaxial lead-in from the rig at the shack, I'm not sure what these $40 products do for us. Are we faced with unplugging our PL-259s each night?

What do you guys do, and what do you use yourselves?

Thanks in advance,

Yes I want to send one bit of binary information.If it is more than one
bit also no problem.
Which type of transmitter and receiver i can use for sending one bit
or one byte of information from sender to destination. The distance
between sender and receiver is 2 Km.

Source
|<----------------2Km----------------------------->|Destination
I want to know about such a devices for transmitting and receiving.

Thanx in advance,

Regards,
Sreenivasu.

>walk between school and home in the snow, uphill both ways.

You forgot BAREFOOT, Freddie. :-)

So, you "spewed RF throughout the world" over 50 years ago?

Unidirectional? I started in February 1953, HF beam patterns
pointed in many, specific directions...thanks to the United
States Army Signal Corps. :-)

>Just as sure as these words are on your screen, you too will someday be an
>old fart just like me.

Poor baby, born in 1939. Tsk, tsk, tsk. That makes me 6 or 7
years OLDER than you, Freddie.

>As you enter the dotage of your life, health concerns
>and the condition of your aged friends, becomes more of a concern. We, like
>you, used to talk about more contemporary subjects.

WTF? Freddie boy, just WHO are you posting to? [see the bottom
since you didn't format this for proper quoting and replies]

>Unlike a number of you,
>we allowed the older folks to have their conversations without ridicule. It
>is called respect, and is a two way street.

Freddie, you are demanding ONE WAY driving on a two-way street.
When did you last take a driving test? :-)

> Realize that when I was a newby,
>I suffered the same as you at the hands of the old farts.

Poor baby. Snif, snif.

>They believed that
>for you to enter their group, you should first show respect and learn to
>snatch the pebble from their hand.

You mean DRINK in their hand, don't you? :-)

WHY did "your elders" have PEBBLES in their hand?

>None of you started in your working life as the CEO of the company, yet many
>of today's generation feel that a newly minted license conveys total
>knowledge. What you have is a license to learn, take advantage of it and the
>brotherhood will naturally follow.

Sigh...Freddie, you may be too far gone in your dotage? :-)

NOT in THIS group in this Din of Inequity, Freddie. Ain't
NO "respect" unless one is a devout morseman worshipping
at the Church of St. Hiram.

>If we all took the time to show each other respect, and be less quick to
>judge, not only would ham radio be better, but our lives as well.

Whoopee, a MAXIM! You ARE in the congregation of the Church
of St. Hiram!

I am supposed to "respect" you for your 'age?' :-)

So, does your quaint little pebble-filled maxim work the
OTHER way, Freddie?

When are YOU going to show respect for those OLDER than
YOU? :-)

[watch out, I have lots of 'pebbles'...:-)]

> won't do real tests.
> ...
>
> Dan

Dan, N3OX, please no flames. That is not the correct style here ...

You are criticising by error, or by ignorance.
I did the measuring of the efficiency by feeding the RoomCap antenna
with 1 KW HF,
havinga VSWR below 1,1 and the result: Less than 70 W heat is produced
by the
antenna, and, as energy can not be destroyed, 930 W was radiated by the
antenna.

The definition of efficiency by the IEEE is:
"The radiation efficiency of an antenna is the ratio of the total power
radiated by
the antenna to the net power accepted by the antenna at its
terminals."

You can measure these data your own, using your instruments in your
laboratory.
The construction plan is available. You get it a a very moderate cost,
for 30 Euros,
as contribuiton to the development costs.
This is less than you pay here in a restaurant for dining with a drink.

And you call that "business". Please keep realistic and study before
you accuse me of what you did.

Regarding the tests on 160m you commented:
I was testing between 22h and 24h local time, during the last weeks.
At this time no oversea stations were reachable due to the present
conditions.
Even the biggest european stations were calling CQ DX, using Kilowatts,
without
any reply from DX.
When calling on 1933 Khz, a pile-up of UK stations appeared. They all

wanted to
contact me - and gave very good reports. Ask John, G3WWM and Eric,
G3IMX
who are very familiar with the 160m band with decades of experience.

Also be aware that unless you place the preamp at the antenna you are
unlikely to obtain any system improvement unless the NF of the preamp is
better than the rig's front end NF.
By placing the preamp at the antenna it will overcome/mask the loss in the
coaxial cable and system NF will be determined by the preamp.

Some very interesting information on that subject is contained
in: "Class Notes: Tesla Coils and the Failure of Lumped-Element
Circuit Theory" by K. L. Corum (KB1EUD) and J. F. Corum (K1AON)

http://www.ttr.com/corum/index.htm

More very good information on RF coils is found in an IEEE
paper by Drs. Corum at:

http://www.ttr.com/TELSIKS2001-MASTER-1.pdf

It's hard to look at the Figure 2 diagram of "a capacitively
tuned resonator" and not see a 75m mobile antenna with top hat.

Equations (32) for velocity factor and (51) for characteristic
impedance are of particular value to amateur radio operators.

Having a good approximation for characteristic impedance and
velocity factor for a bugcatcher mobile loading coil allows
an understandable analysis of a mobile antenna system. I'm
working on a web page based on those two papers.

CW on six meters is live and well. Many use it to make weak signal contacts where SSB is too weak. During the peak sporadic E season -- lots of CW activity across the USA and some DX.

I hear very little CW practice QSO's. but it is a wide band - so lots of room for that. For skip, the band can drop in and out rapidly - so CW practice would best be accomplished by Line-Of-Sight, make a sked with a local and pick a frequency below the 50.090 CW Calling Freq -- for freq useage see URL:
http://ac6v.com/hambands.htm#50

During contests -- lots of CW Contacts also.

For info on when the band is open -- see URL:
http://myweb.tiscali.co.uk/g4ucj/html/6_metres.html

More on six meters at URL:
http://ac6v.com/hambands.htm#50

What some do for pressurizeing coax is (like
Andrew), run an aquarium pump , thru a canister,
that is filled with dissecant (moisture
absorbing), and then to the coax . Also, can
use compressed nitrogen, or another thing,
would be canister of air conditioner rechargeing
material (used to be cheap, but now,??),
as info, Jim NN7K

Hello Felix,

Reading your text, I also get a somewhat unpleasant feeling.

As I mentioned in my first contribution, A good GSO is not a representative figure for efficiency, because the difference between 10% and 100% radiated power is 10 dB.

I am very curious to know your test setup for assessing efficiency. For me efficiency is ratio between radiated output and input. Matching networks are considered part of the antenna.

At low frequency, determining efficiency is difficult. You probably must hire a helicopter to determine the 3D radiation pattern, or you must rely on "traditional antenna knowledge".

In some cases the efficiency may appear to be higher (based on loss measurements). If your antenna is close to a structure that has reasonable coupling to your antenna, It may act as a re-radiator (or absorber).

I like people that don't follow straight paths; many times it resulted in better products or better understanding. However, when you claim a certain efficiency, you should fully state how you measured efficiency and under what circumstances to enable review by others.

I am a little bit skeptical to efficiency claims, especially when I have to pay in advance. I was professionally involved in measurements of very small UHF antennas with wide band, high efficiency characteristics. In most cases the measurements against standard antennas did not show the characteristics claimed.

I believe you should give more details about your antenna (mechanical and electrical).

Best Regards,

Wim

When 6 Mrs is open the CW is usually around 20 wpm, or faster. It is
an excellent band to chat or practice on locally, though. For just
developing skills in QSO at the lower speeds, the old 40 and 80 meter
novice bands are probably still the best place to hang out.

Hi Felix,

Given your statements that follow, it appears that Dan IS criticizing
about error and about ignorance:

>I did the measuring of the efficiency by feeding the RoomCap antenna
>with 1 KW HF,
>havinga VSWR below 1,1

Your claims are based on very thin technical knowledge - and your lack
of experience shows. VSWR is not an indication of efficiency - far
from it. I seriously doubt you know how to measure the V of VSWR.
Your meter measures power, not V. Your understanding of the SWR
versus efficiency relationship also reveals a lack of basic
understanding. For small antennas, low SWR can be solid proof of high
inefficiency. The simple fact of the matter is that no small antenna
presents a load that is remotely close to any standard transmitter's
output Z, nor any commercial transmission line.

I fully expect you will attempt to claim matching solves this. When
you do attempt that, we will clear up your lack of experience there
too.

>and the result: Less than 70 W heat is produced
>by the
>antenna, and, as energy can not be destroyed, 930 W was radiated by the
>antenna.

In fact, you do not prove you measured 10W heat, nor 20W heat, nor 40W
heat, nor "less than 70W heat." You cannot even prove you radiated
930W watts. There are methods to "prove" these claims, and you don't
show any knowledge of those basic principles. Relying on one
definition (poorly extracted from a text) is not sufficient. It may
qualify for sales, but this is not a sales group and you are not going
to find customers here with your poor quality of discussion.

This leaves us with one question: "What do you expect to achieve
here?"

"Unlikely to obtain any system improvement" is a gross simplification,
and not true in most cases.

>By placing the preamp at the antenna it will overcome/mask the loss in the
>coaxial cable and system NF will be determined by the preamp.

Another oversimplification.

Back to the original question, if inserting a wattmeter added 0.1dB
loss for instance, the effect on system Noise Figure of insertion
prior to the preamp will be quite small, even for the hottest preamps.

The argument by another person that wattmeters shunt the DC feed to
the preamp is also a gross generalisation, most VHF/UHF wattmeters do
not interrupt the DC continuity, and do not shunt the line with a DC
path.

Elsewhere, I have seen an argument that the diodes in the direction
wattmeter sampler create substantial intermod products that are
re-reradiated and detectable nearby. I have never seen a workup of
numbers that supports this, and my own estimates are that it is
probably insignificant.

Hi OM,

Good question. One that the free version of EZNEC should handle.
Given that X can vary considerably (and only you know where you want
to start), there must be a multitude of right answers. Also, each of
those multitude of right answers is probably going to have unique
lengths.

If this worked, we wouldn't need trapped tri-banders.

A 10m signal at X will test the three possible paths
and take the 20m one because it is a lower impedance.
The two shorter ones have very little effect at any
frequency.

The reason that real fan dipoles work is that the 10m
signal sees a low impedance at the feedpoint which is
not the case above.

I am thinking about building an ANTENNASCOPE, see fig 1 at
http://digilander.libero.it/hamweb/risorse/antennascope.htm
. This one doesnt allow you to measure impedance but i thought if I replaced one of the capacitors in the bridge circuit with a variable cap of about twice the value I could at least tell if an antenna was inductive or capacitive by which way I had to adjust the cap to get a perfect null. I think I have most if not all of the parts.

Jimmie

It looks like you are going to develop an instrument to solve the
problem, when you should be able to solve it with a little ingenuity
and the VSWR meter that you have.

Source record: 52649

There's no fixed limit. The closer together the conductors are, the more they'll couple. The coupling has two major effects. First is that the resonant length of one wire will depend on the lengths of the others; in particular, shorter ones will be affected by longer ones. So tuning will be tricky and somewhat interactive. The other is that the antennas will be more narrowbanded than when the wires are separated farther. So you get to choose whether to space them closer and have the effects of increased coupling, or space them farther apart and have them be more independent.

4214. Second hand equipment wanted

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-14 04:15:29 UTC
From: David <websales@orbitcoms.com>
Message-ID: <BH4Og.28616$rP1.20259@news-server.bigpond.net.au>
Source record: 52651

I am having trouble here in Australia finding reasonably priced second hand RF test gear.

Anyone know of someone who may be selling any of the following items ?

Sinad Meter
RF millivoltmeter or high impedance RF probe
HP8405A vector voltmeter or similar
Audio distortion meter
Tracking generator to suit HP8569B spectrum analyzer

Thanks

Regards

David Huisman

Hi David

One of your best sources is large telcos going out of business!
(Probably useless to you but worth checking)

When One-Net (I think - or was it a Lucent project - cant remember) died maybe 3-4 yrwars ago they had big auctions to get rid of their gear. The company I was working with at the time had a huge windfall of real good stuff.

Cheers Bob

Its a great site if you want no name connectors and coax so bad that
radio shack would be ashamed to sell it. I see that he no longer posts
his e-mail address in his spam. He's a foul mouthed pain in the ass.

Hello, and if you're a good enough salesman and have at least one university professor to explanation your "interpretation" of electromagnetic theory, you could rename the antenna "Son of CFA" ;-) At some point, however, a prospective customer is going to require some verifiable test data.

All kidding aside, the challenge is the use of technique(s) that allows for the direct or indirect measurement of radiation resistance and loss (structure including any earth loss in the vicinity of the feedpoint) resistance over the operating frequency range. A measurement of the real (resistive) part of the antenna feedpoint impedance can only provide the sum of both types of resistance. We know how much power is being dissipated (heat + radiated) but that's all we can know from this one measurement.

There is also the shape of the radiation pattern...but that is another matter. Sincerely, and 73s from N4GGO,

4225. Odd Question

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-14 20:42:21 UTC
From: Dave <W1MCE@comcast.net>
Message-ID: <h6ydnUnvlrUwI5TYnZ2dnUVZ_tqdnZ2d@comcast.com>
Source record: 52662

I received this from another group and have not seen an answer. Anyone care to comment?

"Good Morning DX List:

Here is the technical question of the day. I have a 70 foot tower, shunt fed at 31 feet with two parallel lines of #6 plastic coated copper wire. The lines are approximately 15 inches apart. These lines tie back into the tower at the high end with pieces of aluminum tubing around .75 in. in diameter, and are tied together at the bottom which is the feed point. The wires are each approximately 6" from the tower legs.

The question: Can these lines be considered as one piece of wire, and if so, what is the combined diameter of the wire? Think back to the days when "cages" were built to increase the effective diameter of antenna wires.

73,
Mike, W5UC

It's called "sarcasm". Keep trying, you'll get it, eventually.

You see, Cheney's daughter, the lesbian, would not be "invited" into the military because of her "orientation". This poses a problem for the Right Wing who wishes to deny the existence of gays and lesbian (at least politically)...so, the issue of gay freedoms is spawned by the very folks who deny them. Those folks are "bigoted" Conservative Republicans. A conundrum, sort of.

There, the "SARCASTIC" voice of liberalism now speaks out"

I'll agree with you 100%. I have a Tech license and enjoy the hobby very much. I plan on upgrading to General once the code issue is settled. I have always heard that "If you don't use it, you lose it". I have no interest in the code so why should I not be allowed to enjoy Ham radio. BTW, my CB license years back was KLW4194..

Felix,

I apologize for the strong language.

I would believe that you've designed and built a quite good mobile antenna that impresses veteran topband operators. However, it's not turning 93% of the power you're feeding it into radiation. I barely believe that it might be taking 7% of the power you're feeding it and turning it into heat in the antenna, but what about the ground return losses in the earth? These are, of course, proportional to the square of the current flowing in ground system. You seemed to suggest that your method of matching to the low radiation resistance is practically lossless. Even if this were to be true, and there were no loss in the matching network or the antenna conductor, you still must have a connection to earth. If this connection is not perfectly conducting, pushing all that current into it will result in high losses. For a ground system with 1 ohm of ground loss, and an antenna radiation resistance of 0.2 ohms, assuming a lossless matching network and radiator, I get an efficiency of 12% over PERFECT earth. Taking the ground reflection losses into account over average ground, it's about 5%. This is assuming PERFECT matching network and a very good (maybe impossibly good?) grounding system. The ground return current has to flow somewhere, the matching network I'm assuming is a black box. It doesn't matter what it is or how novel it is, the ground return current has to flow in your grounding system, and with an antenna as short as yours, that's a LOT of current. You do realize that if you were completely losslessly feeding 1kW into 0.2 ohms, the antenna current would be 70.7A, right?

You won't notice a kilowatt's worth of power dissipation in your car and the earth around it.

Felix, are you willing to do an experiment? Feed your RoomCap antenna against another one as a dipole, adjust the matching network for a good match, and feed 1kW into it and measure the heat produced in the matching network and antenna, if it survives long enough to do so.

And another thing, Felix... even a full size, perfectly conducting 1/4 wavelength monopole with a practically lossless place for the ground return currents to flow doesn't radiate more than about 30% of the power applied to it anyway over average earth. The ground reflection losses in the Fresnel zone dissipate much of the power. This is better over better earth of course, but I doubt your antenna has some sort of control over the soil conductivity and permittivity for tens of wavelengths in every direction. You may wish to revise your claims of 93% efficiency down to 93% efficiency relative to a full size ground

mounted 1/4 wavelength monopole; it would be a more convincing untruth.

One further comment: I have a hard time believing that these are all innocent mistakes.. It reflects badly on your character to make vague, inaccurate statements about a miraculous antenna and then tell people they need to dish out 30 Euros just to be able to try it. My apologies for thinking you're a big scammer if you are merely a victim of your own optimism.... I could see the argument that only 70W are being dissipated in the antenna as convincing even the innocent experimenter that he was on to something big! However, now you know the truth. If you revise your claims with an eye to the reality of feeding a small antenna against the earth, then I won't be so upset with you.

It is counter to the ham spirit to mislead people in this way, if that's what you're doing, and only you know that. We are all trying to learn RF engineering in our spare time, and it's important that the new hams out there take their 38 bucks and apply it to their inverted L project for 160m, or a copy of ON4UN's low band DXing book instead of handing them over to you for the plans to one disappointing antenna.

73,
Dan

Great advice Dan. That book, in my opinion, is the finest book ever
written concerning practical information for the HF operator. And I
have read them all.
You know, one thing that impressed me (and there were many) in that
book is where he admitted that previous versions were wrong in telling
us there was benefit to sloping the end of a Beverage antenna down to
the feedpoint. Simply running it vertically down is the same. To
readers of this newsgroup, if you have only read previous editions,
you should get the new one. It is completely rewritten.

hi

kinda recently i stumbled onto a web site or article (ad) from someone
that was making a 12v regulator that took 12v from batteries to supply
your rig w/a more stable voltage

I lost that link and can't seem to find it or google it

anyone happen to have it??

thanks

Okay, I have received my AOR DS3000A and have the following items to report about assembly.

1. The assembly instructions don't square with the package contents in a couple ways:
a) there's a small package of lock washers included, but no mention of their use;
b) two screws securing the support mast to the mounting are mentioned, but one is included for the two holes in the mast and screw points in the mounting. To install the support mast as described you will have to drill an additional hole at the place corresponding to an screw site.

2. More of a problem is the fact that screw points in the mounting are directly under antenna elements angling down, preventing installment of both for lack of clearance. Either you install the antenna element and try to use another mast screw that's short enough to allow clearance from the antenna element; or you install the (single) mast screw and leave off the nut on the antenna element.

I'm disappointed in this kind of poor engineering and careless packaging, but maybe I can work around these cosmetic problems without sending it all back. Will update with comment about how it performs after a while. bookburn

Hi Myles,

That may be a blessing in disguise. A linear regulator will always exhibit a lower voltage out than the voltage in. If you have 12V in, you cannot have 12V out. It would have to be less. An expensive one might offer a drop of tenths of a volt (11.6V to 11.9V out from 12.0V in), but this depends on the current draw. Most Ham equipment is not rated at 12V, but rather at 13.6V which is the potential of fully charged batteries (2.25V per cell). The "12V regulator" you were considering could easily drop the difference (1.6V) in an effort to maintain a constant 12V. This is not a boon to maximizing output power if that is your goal.

A switcher style regulator can be more efficient, but it will cost much more too. Switchers can take a considerable range of input voltages and supply a fairly consistent voltage at many loads. There are switchers that can supply MORE voltage than what is applied to their inputs, but at a cost of demanding MORE current from that source. Think of switchers as a see-saw that exhibit a constant of proportionality in power (less some loss). For instance, if you needed 12V @ 20A, your switcher could convert it from 6V @ 40A, or it could convert it from 24V @ 5A. [Actually, no one switcher design could accommodate such a wide range with equal efficiency, but there are designs tailored to either situation.]

However, if you demand too much current from your source, then no regulator is going to supply it and regulation is going to fail.

Often, the best use of regulation is to keep circuits from going haywire if the voltage droops excessively during transmission. Unfortunately, during transmission, this is a condition of maximum current demand. Basically, if your voltage droops too much, the battery is either shot (bad cell) or under capacity. Get a new battery, or get a battery with more A/H capacity. This alone could make up the need for "regulation."

No, I don't although I recall seeing such an item in a recent magazine.... CQ or QST?

However, why bother to overcomplicate things when simple will be better anyway. As Richard Clark indicated, if you use a healthy, and properly sized battery, you can't get any more pure DC than that. Float it with a well regulated power supply at 13.6 volts and you'll have what you're looking for.

Just acquired a new motorhome . . . our first. I'll be planning on installing a two meter radio in the cab area (it a Class C motorhome), and would also like to put an HF antenna somewhere on the rig.

I have very little idea what the norm is for mobile operation antenna installations on these fibreglass body rigs, no do I have any idea at present where coax lines are run and routed into these rigs. I can probably figure out something for fixed operation, but not sure on mobile. Any suggestions?

Ed

As to 2 meters, Ed, IF on a fiberglass body,
Larson makes their "OS" series of antennas,
which are essentially a base loaded 1/2
wavelength,and work well on non-metalic
bodies. These are also suitable for
marine use, as well as in the fiberglass
canopies of Blazers, and Broncos! Might
check their web-site. For HF, I would expect
that a screwdriver. mounted low on the body,
in close proxsimity of the frame (for a
good counterpoise), and towards the back
of the vehicle would be the best, tho
if there is a generator, that might
provide noise interference. Also, be
sure to check ALL of these before makeing
permanent, for RF interference TO the
Electronic Ignition ! When working, remember
installing a radio in a truck, that was
converted to Electronic Ignition, WHEN the rig
was keyed, the truck shut down (killed the
new system) Obviously, NOT a good situation,
talking while driveing 70 MPH , during
rush hour! You will have to explore the
vehicle for wireing ducts, and also, IF
it has a catalytic converter, keep wires,
includeing coax away from it, even if inside the
vehicle (above it on top of the floorboards).
Obviously, this doesn't cover all applications
but, should be a good starting point-- Jim NN7K

A small dual-band magmount will get out nicely. Mounting and counterpoise
can come both-at-once. Get some fixture adhesive from the hardware store
and lay down a glob on the roof. I guess you can use RTV or caulk, but I
never tried them. Then, take a steel TV tray or some other piece of sheet
steel about two feet across and push it into the glob of fixture adhesive.
Presto! Mag mount sticks to its counterpoise. If I were you, I'd check for
magnetic properties and VSWR before even opening the fixture adhesive. What
worked for me might not work for you. Aluminum is no good -- nonmagnetic --
and some variants of stainless steel are also non-magnetic.

Just what makes a person an "asset to the ham radio service"? That
sounds just as stupid as an "asset to the telephone service". Like it
or not, ham radio is just a means of communication that has world-wide
reach. Listen up, the "ham radio service" isn't some illustrious
organization. It's just a means for people around to world to chat
live. It can have great value in some emergencies, but most of it's
use is idle chatter.

dear rich:

Hi , thanks for the reply.
the device i saw sure was a switcher"" i agree re:analog yuck

my goal wasn't so much strictly max power per say but to keep power
constant, so if my , on batt power had to be 75w vs 100w i could live
w/that but as the bat voltage droped so would my 'power' etc and
perhaps add a little ''unpredictability'' kinda

my presumption was the regulators would be at least 86% efficient,(manuf
spec's) while not great i figured if i simply got more batteries as
soon as i put load past a certain run time volts would sag w/o a reg

so the question sorta became do i add more battery to compensaate for
the loss of 'regulator' to get the time i need or simply just pile up
the batteries

right now i figured 4--8d sized gell would do the trick w/a little
help from a regulator

whcih do you think is most efficent?

Togethere wih a fellow amateur I am trying to design an endfeed halfvawe vertical antenna for 50 MHz.

We have encountered som problems regarding the impedance match in the feedpoint. I have surveyed the ARRL Antenna Book and Antennebuch (a German antenna book very popular in Europe). The properties of the antenna and its impedance is well understood. The missing point is how to realise the matching network

In order to avoid reinventing the whee: Does anybody have some good links to study practical realisations of the matching network?

Go back to the ARRL antenna handbooks from the 1970's or 1980's... Look in the chapter for HF antennas for 160 and 80 meters... Somewhere in there will be the diagram for an end fed long wire using a parallel tank circuit - an inductor and a variable capacitor in parallel... This will work just the same for your end fed half wave vertical on 6 meters...
The bottom end of the tank circuit goes to your ground/radials... And the top end goes to the bottom end of your half wave vertical wire... Your transmitter coax has the braid going to the bottom end of the tank circuit and the center feed of the coax is tapped up a few turns from the bottom of the coil to match 50 ohms.. Use a few turns of the coax as a choke for common mode currents on the outside of the braid... Obviously you will not be using components with as much inductance and capacitance as you would for 160 meters... As a guess I would say that for 50 mhz you will be tapping up roughly between 3/4 turn to one and a half turns from the bottom to get a match... This of course depends on the form factor of your coil, i.e. short/fat versus long/skinney.. Trying this on your work bench is the best way.. Make up a coil from #14 AWG solid house wiring and a variable capacitor, use a length of the house wiring for the radials and vertical and experiment...
Another method is the J Pole matching system.. Look in chapter 18 of the current ARRL Antenna Handbook...

cheers denny / k8do

An endfed halfwave has inductive reactance, ISTR. If you add another 1/8 wave to it, you reverse the sign of the reactance, thereby allowing an inductance to tune out the reactance. Ground one end of the inductor and tap down with the coax center conductor for a 50 ohm match--Voila! A 5/8 wave vertical!

I had quit following this mundane thread for a while, looking in only on occasion. I must wonder - it is being "recommended" "apparently" by "slow code" to raise the CW rates to 13wpm General and 20wpm Extra.
DUH - we "were" there already.

I've said before and I'll say it again. I'm not a "code" lover, but I've learned it and used it and sometimes listen to it. Will it save a life? Probably not - but still - the chance is there just the same as for any other mode. You use what you have available. CODE did NOT keep the crap off the ham bands, so to put it back in or KEEP it in, is sort of useless to argue about. While "I" think 5 wpm is about as easy as you're going to get - it seems far too many still cry about it. Yes, you could make the written tests tougher - but that sucks too - because in a sense - they're "not" any tougher when you're being given the answers in a book. And most of those books cover "just" enough to pass the exams - they by no means "teach" you electronics. In days gone by - you had to have at least a basic grasp of electronics to be able to pass the exams. I'm not saying you had to be a "Technician" with years of experience - I'm saying you had to know more than these books teach. At that time - you had NO clue what the FCC would ask. I've still got sample study guides sent by the FCC if asked - and they were "vague".

CODE, EXAMS - nothing will keep the riffraff off the bands. This is a lawless society anymore - people do as they damned well please. CB got quiet in many areas not due to Cell Phones - it happened long before. It happened in many places based on what I've learned - because of the garbage. Ham will be the same way if it isn't respected. We're in a NO WIN situation.

I find it amazing, people with illegal amps and radios will defend them to the hilt - like a murderer caught with a smoking gun - claiming his/her innocence. If the government agency deems them illegal - then they are - no

excuses. Just like the speed laws - if the road is marked 25, that is what it is - plain and simple. If we all took responsbility for our actions - maybe things wouldn't be so damned bad. I know lots of cbers who got out of cb BECAUSE those with the illegal amps and radios "splashed" so bad, they couldn't even talk on the radio. So, tell me again - how those illegal radios and amps are helping? Hams have a rule of using the minimum necessary to carry out the communications. IT DOES WORK! QRP (Low Power) is part of the challenge! 500- 1000 watts or more - any dummy can do. If you want to be known as an "Alligator" station - ALL mouth and NO ears.... keep using that garbage. Who wants to talk to them? That is as irritating as static on an AM radio station. Listen to Channel 6 on the CB - there is a guy who constantly talks - HOW he hears anyone is beside me. I think he talks just to hear himself talk. AND being he is in the south, he has to be running some power. If everyone operated like that, the bands would be total chaos, no one talking to anyone - only to themselves. How the FCC hasn't busted him yet - is amazing.

Just my 2 cents.

L.

Google WB6BLD. Or just go to http://tonnesoftware.com/piel.html Jim has design software of both Pi and L networks that will perfectly match the anticipated impedance to 50 Ohms. Other interesting Amateur Radio associated software as well and free student versions.

Hi Myles,

86% seems rather poor for a switcher that is dedicated to 13.6V (or
lower) in and 12V (or higher) out. I would have expected it in the
90s.

>so the question sorta became do i add more battery to compensaate for
>the loss of 'regulator' to get the time i need or simply just pile up
>the batteries

Depends on the quality of the batteries and how close they track.

>right now i figured 4--8d sized gell would do the trick w/a little
>help from a regulator
>
>whcih do you think is most efficent?

I agree with, and use what Ed suggests. I have two batteries floating
on a 20A capacity power supply. Each battery and supply are fitted
with high current connectors (the battery connectors used in electric
lift equipment). They also have additional high current connectors to
fan out to the equipment. Don't forget inline fuses.

My batteries are built from Hawker-Gates SLA CYCLON cells:
http://www.batteryweb.com/hawkersla-detail.cfm?Model=0820-0004&label=singlecell
which have 25 A/H capacity. This configuration allows me to swap
batteries and cells. The cell swapping, however, is only on the
occurrence of its failure, not as a routine.

The two batteries (no supply) were enough power for light duty over
field day weekends.

Remember the "No child left behind" policy of our educators of some years ago? What you are seeing today is largely a result of that philosophy. No responsibility, accountability or respect for others or oneself.

I worked as a radio dispatcher in the Air Force during my Sixties tour. That was the foundation of my radio experience. I owned a CB set for a year before I actually transmitted. The style was so alien and "cutesy" it made me want to barf. Then the syntheisized 40 channel rigs came out and everyone could afford one. End of CB for me.

I then went on to get my commercial ticket with radar endorsement. A year later I got a ham ticket and two years later I got my Extra. Code does not come easy for me. It was a constant uphill battle to pass the 20 wpm code test. But eventually I passed it.

Turning on the radio today, there are still some good folks on ham radio and not all of them are old timers. But a lot of the same types that ruined CB and now ruining ham radio. I can't remember the last time that I actually transmitted with my station. I'm about ready to sell it off and chalk it up to history.

Amplifiers are not intrinsically bad. Abusing amplifiers is bad. If you work 75 or 80 meter telephony, an amp is an absolute must have, especially if you have a less than full size dipole at a decent height.

I enjoyed ham radio more when folks knew a bit about electronics. It gave us something to talk about that we all hand in common. Ditto CW. No one had more trouble learning CW than me, believe me. It still gives me a headache to operate CW for more than a few minutes, but I wanted that Extra Class ticket and that was the only way to get it back then.

Thanks for the above suggestion. It certainly would work but for the fact that I am a "neat-nick" and a former professional in Public Safety radio maintenance..... thus I tend to shy away from this type of installation (not that there's anything wrong with it). However, I will certainly keep it in mind should it become necessary. Tnx agn.

Not really, the capacitor goes on the end of the coil closest to the higher impedance. I'm certain his half wave will be appreciably above 50 Ohms. Mine's about 2600 Ohms.

I honestly can't tell whether you are being facetious or not, but you've struck upon my rawest nerve.

Whatever happened to personal property rights in the US? Since when can't a person do anything within reason on their own property? CC&R's were originally meant to keep people from stacking trash a mile deep or parking junk cars on their lawns in perpetuity. This is fine. When they started telling people they couldn't have a TV antenna, satellite dish or ham/cb antenna, as well as what color they could paint their house and whether they could have a tacky lawn gnome, I think they went too far. People are far too easily offended by the stupidest things these days. Grow a SKIN, folks. It's a free country (debatably).

For the "L", it depends on the Q of the "L" network. You're not in charge of that, you have to take the Q that the transform gives you. With a constant inductor value, I can get pretty close to 1:1 clear across the band just by varying the capacitor value for the frequency. Of course, if you don't have any adjustable "C", YMMV. I'd think you need to get to a pretty high frequency before you didn't have to add "C" to whatever exists, but the big advantage of Voltage feed is that the current to the "Ground" is minimal. When you don't know that your ground is zero Ohms, you're better off putting as little current into it as possible.

<<how did you come by this kinda cable?

right now i am using gold 100amp lugs crimped to 10ga wire, prob not the
least resistance but my distaince is 10ft kinda long but on the radio
side i can't terminate 10ga to my little powerpoles i'd hate to pluck
strands off to ensure a fit/crimp

i could make a pig tail adapter but i dunno if thats a good idea feeding
a large ga cable then going to say a 1"step down stub naturally my
draw will be appro for that size wire but still

Good luck with it. :) You'll find CW is fun, rewarding and will add to
your overall enjoyment of ham radio. See if there are people in your area
that do on the air code practice sessions. If you have an HF receiver, you
can tune in CW transmitions on lower portions of the bands.

Believe me, I'm not "knocking" amps, just the "evidenced" misuse (abuse) of them. Yes, they "do" have their use and place. But most of those using them "THINK" they have to "rule the airwaves" to converse. Their splattering ruins it for ALL.

I am curious as to what the expected use will be. I am not familiar
with 6m in Europe, but 50 megahertz vertical in the US is not something
you will work much on.

If you are looking to work SSB on 6m, you will be better off with a
horizontal antenna. There are many easily built 6m beam plans available.

FLoat it with a well regulated power supply at 13.6 volts and you'll be mopping up boiled-out battery acid a lot. 13.4 is the highest I'd go on a float basis. 13.6-13.8 on an intermittent basis.

All I can say is that while working the last 32 years for one of the countries largest Telecommunications Organizations, we floated all our thousands of communications battery banks at 13.6 volts with excellent results. No batteries dried out prematurely due to this float voltage... in fact that is the figure recommended by a number of top battery manufacturers such as Exide, GNB, C&D Technologies, etc.

> relative to the actual frequency.

Yes. I have built three copper-pipe j-poles for 6 M. The overall length is about 13 feet (4 meters) long. I made them predominantly from 3/4-inch copper water pipe, which comes in 10-foot lengths in the US. I used a reducer and about three feet of 1/2-inch pipe for the top part of the long section. All of the connections are standard water-pipe fittings and the soldering is with a propane torch on sanded and fluxed surfaces. These three are among about twenty j-poles I've made for VHF/UHF. They seem to be indestructible.

I was able to match about 80 percent of the 6 meter band under 3:1. My best SWR was about 1.2:1 with a short length of coax and nothing special at the feed point. A choke consisting of four turns of the coax is recommended for decoupling.

I am a j-pole lover. I intend to try a flagpole or two at HF, someday.

<how did you come by this kinda cable?

Hi Myles,

Just wire. Speaker cable if I recall. Its the connector plugs that
are what I paid attention to. They are properly called "anderson type
disconnect" or "fork lift connectors." The specific SMH boxed part
no. is SY6319G1. An example is found at:
http://www.electricvehiclesusa.com/product_p/ds-124103.htm
and is rated at 50A.

>ive seen these batteries alot so to get
>12volts (ish) you have to put them in series so then you only end up
>w/25amps no? and i am guessing your load isn't 25amps

In series, yes. A standard configuration.

The load can be intermittent to 25A, and it is the peaks that can pull
the voltage and push a circuit into reset. One of my rigs is a Drake
TR7 that I had to rebuild. It will output 150W.

>my goal was to get a few days of normal op on battery a little math
>showed i'd need to dedicate a room for the batteries and my budget will
>go bust just on those 2 d sized units which i havn't found around nyc
>'used'''

That's hard to believe, especially when I found two batteries for the
price of less than one cell. (Of course, I also get to rummage
through a store called Boeing Surplus. Avionics trash is other
industry's gold.) Most folks simply buy a deep cycle RV or Marine
battery.

Good morning all

I take the opportunity to answer all of you at once.

Thank you for a lot of suggestions. I had thought about the J-pole the problem however the problem is that we have some glass fibre tubes only about 25 mm in diameter, so we are somewhat constrained with respect to realise a J-pole.

Regarding a groundplane as suggested by some, the idea is to mount the antenna on top of a mast much like an ordinary 2 meter or 70 cm vertical antenna. In these circumstances a ground plane is not feasible.

Tom Ring asked about 6 metres in Europe. In some counties among them Denmark there are few FM repeaters in operation. A number of amateurs have either old army radios or modified Land Mobile Radios (LMR), typically salvaged from taxis, fire engines and so on. All these radios operate in FM. Our idea was to operate in this segment of 6 meter operation, not to operate in the DX part of the band. Together with som fellow amateurs we have also tried 6 metre mobile. It actually works!

vy 73 and once again thanks for the responses

4299. What antenna for receiving video signal from ISS ?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-17 10:54:57 UTC
From: Thierry
Message-ID: <450d2982$1@news.vo.lu>
Source record: 52536

Hi,

I live in Europe. I 'd like to know if it could be possible to receive video signal from ISS (the one usually sent to Houston) when it crosses the sky over europe and display the pictures on a normal TV (not via NASA TV).

Could it be possible to pick up the signal with a normal satellite dish (and of what diameter) and on which frequencies ?
In addition, could the signal be encrypted to prevent any reading ?

I haven't found any information about that on the net but I could imagine that we you are able to pick up radio communication from ISS and NASA can receive their video, it could be also possible to receive the video as well (in the same way at weather imags).

Thanks for your lights

Thierry

While that is true in your country, it is not yet true here. The
international conference simply left it up to each individual country as to
whether or not to require it.

I have a W4RRY battery booster and it works. It is useful to extract the useful charge out of a lead-acid battery. I have an FT-857D, and that gives up at about 11.5V... long before my marine battery is out of useable charge. The battery booster fixes this... of course, if your rig will run properly down to 10.5V, don't use it. It will probably increase your battery drain.

When I was HL9ACT, mobile operation was disallowed in South Korea. All
ham radio was disallowed in North Korea.

Under FDR, amateur radio was Disallowed in America.

Interesting. Liberals looks at drug abuse as a victimless crime, just people need some help, free needles, methadone, and billions in drug counseling and counseling centers.

All their rock and roll heroes and hollywood legends are stoned all of the time.

But when Rush avails himself to to these legal views that the liberals have put into place...

"he's a drugged-out loser."

Rush absolutely should have taken the same deal that the dems set up
for themselves and their "drugged-out" loser children. Wonder why jobs
go overseas? Few in America can pass a drug test.

Nah, they're ALL drugged out losers. Some have lost more than others. Rush
is fortunate in that he got busted before he could do more damage to himself
than just his hearing loss. Most of the rest are at least half brain dead.

4316. Receive Preamp question

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-18 01:31:00 UTC
From: Rod Maupin <someone@someserver.com>
Message-ID: <KJmdnfwLGalOa5DYnZ2dnUVZ_sydnZ2d@neonova.net>
Source record: 52553

I am wanting to buy some receive preamps and am wondering if I'm looking at it the correct way. Here are two examples from two different manufacturers, both for the same band.

#1) .55dB NF, 16dB gain
#2) .9dB NF, 20dB gain

So, do you go for more gain or less NF? Since this is for weak signal VHF/UHF work, I would say go for less NF but you can tell me what you think.

Also, in this example, one preamp handles more power then the other, but I don't care since I'm only going to be running 100 watts max. Both preamps have RF sensing.

Normally you go for the lowest NF. The NF is set by the first amplifier and it should have enough gain to overide the NF of the next stage. With too much gain you could overload the receiver, but unless you are in an are with lots of transmitters it is doubtful you will with 20 db of gain.

The gain can be madeup anywhere in the system but the NF is set by the first stage and anything after that will not help if the receiver is anything much to start with.

Unless you are in a quiet location and are mounting the preamps at the antenna I doubt that you will notice much differance in actual use.

Generally speaking, the BEST NOISE figure (factor,
ect. is what you want (best sensitivity),
however, the Gain would be a consideration, IF
you had excessive coax loss. (in this case, in
excess of 16 dB, which would be quite doubtful.
The gain of a vhf (or any amp, for that matter),
only needs to exceed your coax (and your front end
I.E. Reciever's Noise figure, so as to allow the
preamps noise figure to take precidence (establish
your floor sensitivity) I hope I stated that
correctly. And, even then, as long as THAT noise
figure is below the cold sky noise (from other
sources), then the cold sky noise (about 1.8 dB
on 2 meters) is the limiting factor on your
sensitivity, before figureing the SELECTIVITY of
your reciever (half the bandwidth, gain 6 dB,
half again, now gain another 6dB). Probably
as clear as mud, but the best I can describe it--
Jim -NN7K

Hmmm. A radio personality who railed against drugged out hippies and
"tree huggers" is caught in the act of illegally obtaining drugs for his
own use. Purchasing drugs in a parking lot with shoe boxes full of cash
for his local pusher.

Who is hypocritical? Linearity is a curious concept when applying it to
this obese fraud.

Al Franken had it right: "Rush Limbaugh is a Big Fat Idiot".

If YOU'RE offended that's YOUR problem.

Rod,

The context in which you intend to employ the preamp is needed to
accurately answer your question.

The industry uses a single metric for fully capture the receive
performance of the entire station, it is the Gain to Noise Temperature
ratio, written as G/T. S/N is directly related to G/T, for every one
dB improvement in G/T, you get exactly 1dB improvement in G/T.

Calculating G/T brings to book the NF of your "receiver", transmission
line etc losses, feed system losses, the gain and noise of your
preamp, and the external noise.

I have just explored options for improving my 144MHz station after
polite on-air advice suggested I needed better feedline and a preamp.
In fact, they are quite costly for little improvement, compared to
stacking another beam. See http://www.vk1od.net/gt/144.htm for the
write up and links to a description of the G/T method and calculation
tool.

A further aspect to keep in mind is that it is easy to build a cheap
preamp that exhibits very low NF and good gain in a shielded room. If
the preamp has poor IMD, it might actually degrade the system
performance depending on your own RF environment. Minimising noise
from IMD means better active devices and better front end selectivity,
both of which are high cost items.

So, for a start, read the page, follow the link to the second article,
download the spreadsheet and start populating the model with your own
scenario.

I would encourage a "try before you buy" evaluation of a preamp to see
what it does in your situation, the IMD noise cannot be simply implied

from published specs.

Prophetic! Should have read:

The industry uses a single metric to fully capture the receive
performance of the entire station, it is the Gain to Noise Temperature
ratio, written as G/T. S/N is directly related to G/T, for every one
dB improvement in G/T, you get exactly 1dB improvement in S/N.

As you know from HF, changing the NF of your receiver (by swithing in
the attenuator or turning the preamp off) often does not change the
S/N ratio of signals on the lower bands where ambient noise dominates
system performance. G/T gives you a method of predicting what S/N
improvment you will achieve with each of your proposed preamps (model
each at top or mast of at the tx, change out the coax for better stuff
etc)... and when you assess the cost of the improvement, you might
have different thoughts about what is "best" for you.

In American English, "gas" is short for gasoline. Gasoline is the same as
petrol. The term petrol is generally not used here.

Best way to use this is as a center fed dipole... Make it as long as
you can with equal lengths... A tuner will help with rejecting strong
broadcastr stations...

I think 14.313 is some kind of ham net. The ISS is almost certainly
transmitting digital video via microwave, more than likely encrypted.

Interesting take on this. The local store has one little cabinet and a
part of a rack. They're hardly pandering to those experimenters.

I look at it as more that what they direction they decided to head into
won't generate all that much repeat business. How many times will
customers come in to buy new cell phones? Now that the market is
becoming saturated, and cell phone vendors are becoming as common as
pizza takeout joints, It is hard to blame people like me, who UsED to
spend a good bit of money there.

Interestingly enough, while visiting Ottawa this summer, I walked into
a electronics store (a division of Circuit city, but in a mall
environment) and was shocked to find several walls of parts!

> I bet I've been RS 4 times in a month, each time buying $10 or less in
> supplies. Who can pay the rent on such purchases?

I think that relates to my comments above. Wanna do a lot of small
purchases every month, or sell a cell phone once every two years to a
customer. There *are* a lot of experimenters out there. They now buy at
Mouser or the like.

> Hasn't anyone seen the same thing happen to hardware stores?

Or that Circuit city store. Of course I haven't seen one of those
places in the States! 8^(

> In my area, at least, there are no components, circuit boards, solder,
> etc in the "big box" stores.

> radio. Has it changed over the years? You bet. Why not get out an old
> picture of yourself and look in the mirror. Have YOU changed?

Yeah.... I got better looking.... ;^)

I think to sum up the Radio Shack experience, they were originally the
type of store that sold a little bit to lots of customers. When they
switched to cell phones, they were trying to sell a very little to large
numbers of customers. How many times a year does a person buy a cell phone?

As they marginalized their previous customer base, and now that most
cell phones are replacements, not new buys, the result was inevitable.

I'll miss 'em too. Got several kit radios, a capacitive discharge
ignition kit. several antennas, untold numbers of parts. Stereo
speakers, tape recorders. I used to spend thousands there.

But over the past several years, they've been trying to make sure I
don't miss them very much.

Well I knew this was going to happen. As ham radio requirements continue
to get dumbed down and people only understand how to use a microphone,
groups like homebrew are going to dry up.

Yes, it hinders.

It keeps out the stupid and lazy. Individuals that really don't what to be
hams if it requires knowledge and skill to get a license.

Make them stay on CB and FRS. They're not an asset to the service.

And neither are you.

Up 'til now I have not read your posts- just subject lines.
From them, I gather you are something of a ham radio guru. May I ask a few
qualifying questions?

1. Do you have a code proficinecy certificate - if so at what speed? If not,
how fast can you copy? I would hope at least in excess of 20WPM, given your
posts.

2. Do you build/design most or any of your equipment?

3. Have you published in any of the amateur journals?

4. Are you active in perhaps EME or microwave or other modes that require
at least a modicum of technical expertise?

I will admit that I, and the amateurs I congregate with can answer yes many
times over to the above ( oh yeah, proficiency at 25WPM)
but you don't find any of us ranting about the current state of exams.
Those that wish to use code may, and those that enjoy designing/building
may. Those that don't may want to in the future with proper Elmering.

Looking forward to your response,

Dale W4OP

Either your ISP's usenet server is losing them, (sometimes they drop groups intentionally), or something else is goofy with the usenet handling of this group. I just went to check that group and it came up with no new postings. However, I then reloaded all articles and it showed a several postings made yesterday and today. So, bottom line, it IS still working.

Great response, Jim. Only one nit to pick, that Noise Figure and
incoming noise energy are not equivalent or even really related. Also,
a .1 dB change in NF does not imply a .1dB change in signal to noise or
received signal level. It is a non-intuitive relationship to say the least.

EME and Microwave and till this year all my microwave gear was
homebrew (added an IC 910 h with the 1.2 gig module)

Good luck Dale.

His type has a single point of aim, and a single point of failure. He
probably has no idea how to make a power divider for 432 or a sequencer
for an EME station. Hell, probably has no idea what either one is.

Some people have a single point of view on what it takes to be a capable amateur radio operator. And they could do it with a spark gap transmitter. And couldn't use much of anything more advanced.

BTW, you might be interested to know that VE4MA worked a couple of the
NLRS (Minneapolis) group on 10 Gigs Saturday night on rain scatter. 620
kilometers on about 8 watts CW. Maybe good enough for NBFM, but no one
bothered.

BULLSHIT! Code is NOT KNOWLEDGE!!! I have NO problem learning
technical info that helps me use the radio properly. Code is not
needed to do that.

Get off your high-horse already.

>Make them stay on CB and FRS. They're not an asset to the service.

CB and FRS don't have the range.

>And neither are you.

Who the FUCK are YOU to make such a statement? You snot nosed,
arrogant PRICK! You do NOT know the kind of person that I am!! Wake up
and smell the cappuccino! Code is obsolete! Knowing code does NOTHING
to make somebody an "asset to the service". And, could you explain
what makes a person an "asset to the service"?

What fantasy do you hold that you would believe that your tiny-fisted
tantrums would have more weight than that of a leprous desert rat,
spinning rabidly in a circle, waiting for the bite of the snake?

Waxing poetic now?

Yes it's obsolete. Yes, it's fun.

Should it be used to qualify? Let the FCC decide (soon).

If it is eliminated, will that change the "Service"? Maybe.

Will CW disappear? Probably not.
Historically, it defined ham radio, so it has a special place in the
hearts of very many hams. It's natural that they sort of cling to it.

Will CW's elimination be the end of ham radio? Of course not.
Ham radio will cease when all the hams die off. New hams are needed,
with or without code.

My personal hope is that a significant minority of these new hams will
take up CW and learn to enjoy this mode. It truly is a fun mode. I
hope people will WANT to learn it.

Compulsory things are seldom welcome,,,some are necessary. Is CW a good
requirement for ham radio? I guess it has probably outlived its day.

A requirement related to other digital modes would make a good
replacement. True?

Similar to the Hustler models of mobile antennas, the distance between FP and X would be part of each dipole. FP would be the end of the coax connected to the dipoles.

There's a big difference, Bill. With the Hustler system, the
10m *loaded* element has a lower impedance on 10m than the 15m
and 20m elements, so most of the 10m energy flows into the 10m
element.

Without loading, as below, the 10m element has the highest
impedance on 10m. The 20m element has the lowest impedance
on 10m so most of the 10m energy flows into the 20m element
and the system is non-resonant on 10m.

I used EZNEC to make a vertical inverted-L, resonant on 20m.
It has a 6 foot vertical section and a 10.8 foot horizontal
top section. Then in the other direction at the top, I added
a 2.25 foot section to try to make it resonant on 10m. There
is very little 10m current in the 2.25 foot section. Most
of the 10m current flows in the 10.8 foot section. The
feedpoint impedance on 10m is 522-j719.

On 10m, the impedance looking into a 10.8 foot whip is much
lower than the impedance looking into a 2.25 foot whip.
The 10m energy pretty much ignores the 2.25 foot whip and
takes the path of least impedance into the 10.8 foot whip.

The above transcript is an URBAN LEGEND.

It 100% WILL NOT work as stated.

The full story of this particular amusing Urban Legend is at the URL
below...

http://www.snopes.com/autos/techno/keyless.asp

Wireless Entry devices for passenger cars and trucks use RF.
They do not use audio. Also, the RF signal from a keychain Auto
Remote Entry device WILL NOT carry atop a cellular telephone
transmitted signal.
```

If this method were true and did work as
stated, hackers would sit in parking lots
with scanners and computers getting the
embedded signals off of people's keychains
and the result is vehicle Grand Thefts would
increase 5000% and nobody would want to
own any type of a wireless entry system on their
car or truck.

I am amazed that Bell stated this, as with his background
in ham radio and broadcast electronics, he should have
known this was a crock of chicken beaks....

Think Back, Are todays conversations on 2 meters as technical as they were 25 years ago, or today might you hear things like:

"I woke up this morning with a pimple on my butt" or

"The dog crapped on the living room carpet again."

Allowing no-codes on VHF & UHF has made discussions less technical and more like CB. Don't let your hatred of CW destroy our HF bands too.

Amateur Radio, a National resource.

Yes, you can feed a two wire Beverage at the center, with reflection
transformers at each end. The feed transformer will have two ports,
which will provide directional RX antennas in two directions.

I used one for a few years to good effect on Topband.

I know that it was in Vic Misek's Beverage book, and I think it's
in the ON4UN book as well.

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <12h17gktf0opa87@corp.supernews.com>
Source record: 52506
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.amateur.policy,rec.radio.scanner,rec.radio.shortwave,rec.radio.swap

As a reader and frequent contributor to the rec.radio.amateur.antenna newsgroup, I see a large and increasing volume of messages cross posted to a large handful of groups which have nothing to do with antennas. Not surprisingly, I don't see any of the regular contributors to this newsgroup participating in the endless arguments about Morse code, testing requirements, and what it takes to be a "real" amateur. These threads seem to be increasing in number daily, involving the same participants, and have grown to the point that the signal-to-noise ratio of rec.radio.amateur.antenna newsgroup is getting seriously degraded. It's becoming necessary to fish through multiple off-topic threads to find the postings involving antennas.

There's no point in including rec.radio.amateur.antenna in the list of newsgroups you send these postings to. There are certainly groups whose readers are much more interested in participating or reading about these topics.

So my request is: Please don't include rec.radio.amateur.antenna in the list of newsgroups you send the original posting to. And when replying to a thread whose topic doesn't involve antennas, simply delete rec.radio.amateur.antenna from the list of newsgroups receiving the reply, before clicking "Send". This won't detract in any way from your discussions, and will be a relief for rec.radio.amateur.antenna readers and participants.

Thanks and 73,
Roy Lewallen, W7EL

There's an internal battery in some phones to keep the memory alive if
you change batteries, but it wouldn't actually run the phone for more
than a small fraction of a second. It's about as powerful as the CMOS
battery in a computer.

>> 4) There is also a way to access your cell phone serial number from
>> your keypad so you can write it down. Then you can call the phone

>> but you can rest in knowing that the thief can no longer get any benefit
>> out of it either! :-)

Or just tell the company to disable the phone you have on your account
- they have all the information they need in their database. Although
you CAN get the IMEI of a cellphone very easily.

Oh boy, Roy! I fear you just encouraged them! Once upon a time I posted fairly regularly in the policy group. Then we got a new member who was happy to e-bomb the group with the help of a lot of throwaway addresses. Heaven help ya if he chooses you as a target. I think what happened in policy was that a lot of regulars were chased away, or just got bored with hearing about others supposed sexual deviancy, and of course Morse code testing.....

Of course it isn't any fun for those types if they don't have anyone to fight with. I suspect that the malignancy has just metastasized to the other groups to get more sparring partners. 8^)

Groups trimmed to not be a part of the problem...

> 99.9% of the world ham and shortwave population knows about it...I guess I
> just found the "TWO" that dont LOL!

FYI

I checked the nice ARISS website from Radio Amateurs of Canada at
http://www.rac.ca/ariss/oindex.htm

On the site, updated to yesterday, they give this info:

<quote>
Frequencies in use

The following frequencies are currently used for ARISS general QSO's
Voice and Packet Downlink: 145.80 (Worldwide)
Voice Uplink: 144.49 for Regions 2 and 3 (The Americas, and the Pacific)
Voice Uplink: 145.20 for Region 1 (Europe, Central Asia and Africa)
Packet Uplink: 145.99 (Worldwide)
Crossband FM repeater downlink: 145.80 MHz (Worldwide)
Crossband FM repeater uplink: 437.80 MHz (Worldwide)

All frequencies are subject to Doppler shifting.
<end quote>

Note the total absence of HF. Modest antennas will work the ISS. Haven't
researched it [yet]. However, if 5 watts can work repeaters at 80 miles
using a j-pole, a mobile ought to do the ISS, assuming there aren't a bunch
of big-gun stations calling, too.

What's the claimed QRP record for an ISS QSO?

Sure!

I guess that you were not around during the heyday
of the 14.313 and 75 Meter Jamming Wars of
the late 70's and 80's.

ALL of the QRM'ers involved had a General or better
and in those days you had to pass a 13 WPM code test
to even GET ON the HF spectrum.

Your argument is as pointless as your ball-shaped fart head.

My request is: Please learn about kill files, and please learn how to take action yourself by killing all posts crossposted to groups other than rec.radio.amateur.antenna. You'll have a much greater chance of changing yourself than you will of getting everyone else to do your bidding, and you'll be a whole lot less frustrated once you do figure that simple task out.

I have a theory about hams who can't even master a news reader, but I'll leave that discussion for another thread.

No, YOU are the problem. A proper kill filter will kill all crossposts,
no matter what the identity of the poster may be. If you really knew
how to use a kill filter (and you obviously don't), morphing posters
would present no problem at all.

You also top post, and that makes it obvious that you have a lot yet to
learn about Usenet.

Besides, we shouldn't have to kill crossposted messages. Simply to eliminate all crossposting is throwing out the baby with the bathwater.

The culprit(s) change the threads within the threads, so that you end up feeling like a plate-spiiner, killing one thread, then another, then another. In addition, those throwaway addresses insure that we spend as much time filtering as we do reading.

How amusing that there is an element out there that insist on their free speech to post their antisocial garbage, yet they blame the victims when the victim has the audacity to complain.

Darren-

Take a look at
http://www.channelmaster.com/pages/TVS/MountsHrdwr.htm
for examples of various hardware used to attach antennas to poles and to
attach poles to houses. Many hardware stores carry generic versions of
these items.

If you have a Lowes store in your area, look in their electrical department.

4388. GAP resonance shift

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-20 18:59:41 UTC
From: K&#65533;HB <groupk0hb@earthlink.net>
Message-ID: <xcgQg.14165$bM.4814@newsread4.news.pas.earthlink.net>
Source record: 52525

I have a GAP Voyageur-DX vertical (160, 80, 40, 20M) which has recently shifted its' resonance points.

160 now resonant at 1990kHz, previously at 1825
80 now resonant at 3980, previously at 3725
40 not resonant in band, previously at 7100
20 now resonant at 13775, previously at 14150

The antenna is physically solid, all wires are OK and properly attached, the three counterpoise wires are intact and connected. I have changed out the capacitor buried at the top with no change in symptoms.

Any suggestions?

You need to go to spelling class and antenna theory class.

Additional capacitance would LOWER the resonant point, not raise it.

Mismatched feedline will change the VSWR but will not change the
resonant frequency.

Look at the following web site for related info:

http://www.gopherlink.com/DeltaXray/3x3-Graph-Compare-Detailed.html

Although a monobander and two elements both driven the info might aid in any
evaluations you may have to make. By the way, driving both elements
provides a 50 ohm match See
http://www.gopherlink.com/DeltaXray/Graph-SWR-Delta-Loop.html

Roy. I appreciate your point and I'm sorry for disturbing the
newsgroup. It won't happen again, I promise. I'm glad we have
RRAA because I had antenna questions they couldn't answer over
in rec.radio.cb

Does one long continuous wave(CW) make your antenna warm in the winter?

What kind of antenna do you use to receive CW, a vertical co-linear
ground-plane or some form of half-wave Dipole? What's Best?

Does antenna polarization matter if the CW is high speed and received
with a computer?

A lot of hams now are Appliance Operators and hate CW, how can they keep CW of their antennas?

I heard like if you hook the coax to your dipole antenna in reverse, CW comes out backwards, Like POTS would come out as STOP. Is that true?

Thanks Roy, keep up the good work! You're doing a good job. 73

Living in a small tent rather than a house would maximize the room
available for HF antennas, and be great for VHF/UHF communications from
inside. Best to put the tent at a corner of the lot.

How about making all rooms 20'x20' and stacking them with a slightly larger garage as the ground floor. With the currently popular 10' ceilings, a 3 bedroom, 2 bath house with a den and dining room would bring your roofline to approx. 90 feet. I think one could work wonders with the den/shack as the upper room, especially with a "widows walk porch" going all the way around it. (G) Am only half kidding with this design.

Yes, but he asked specifically about using the fence to
mount a Beverage, so I provided an answer that
applied specifically to a Beverage. Since Beverages
are directive, that's what he gets.

Why would you assume that he doesn't know that a
Beverage is directive? Every web page and every published
reference about the Beverage starts off with a description that
it is a directive receiving antenna.

I'd say build a 20 story hotel on the property with a parking garage
in the basement, a great restaurant, a penthouse suite with a view to
live in and operate from, and an HF log periodic up on the roof. ;-)

Yes, I wanted a Beverage for 160m but did not know how to implement if
I was
in the center rather than the edge.

Questions re your implementation:
1) What is a reflection port, and how is this built differently than
using a
termination resistor?

2) Is the coupling port a pair of 9:1 baluns on the same ferrite core?

Thanks,

The Eternal Squire

4407. Here are the new band designations & modes after FCC R & O comes out.

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-21 23:32:00 UTC
From: Anne Tannah <anne@no.net.net>
Message-ID: <QhFQg.592$o71.428@newsread3.news.pas.earthlink.net>
Source record: 52394
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.policy,rec.radio.scanner,rec.radio.swap

Here is a list of the band designations and allowable modes after the FCC Report and Order comes out eliminating the Code Requirement.

Note: This bandplan has been endorsed by the C.B.R.L., Citizen Band Relay League, 225 Main Street, Newington CT.

Band Frequency Allowable
Range(MHz) Emmissions

CB-160 1.8 - 2.0 Splatter Mode, Echo-mics o.k.
CB-80 3.5 - 4.0 Belching & Farting permitted on 3.950
CB-40 7.0 - 7.3 Splatter mode, 7.2 echo-mic calling freq.
CB-20 14.0 - 13.35 Jamming modes permitted on 14.313
CB-15 21.0 - 21.45 Noise Toys & Roger beeps ok below 21.250
CB-11 27.185 National New Ham calling frequency.
CB-10 28.0 - 29.7 Tweak your CB a bit more and you're there!
CB-02 144 - 148 Farting and repeater kerchunking.

Profanity, insults, and Cursing are permitted if phrases like "Old Extra licensee" or "Morse Code" are used in the same sentence.

Discussions of a technical nature are rarely heard and prohibited anyway.

27.185 MHz is also the prefered frequency for new hams to let out a mating call.

Ten Codes are prefered for brevity.

See ya on the new Bands!

Anne

Art

Yagis, when made of almost anything but something like nichrome wire,
are very efficient. Aluminum element yagis run in the high 90's of
percent efficiency when properly designed.

My bet is that you aren't speaking of efficiency at all, but something
you don't know the words to express. Try to explain what you mean, and
this group may be able to help you.

Thanks all I got the antenna finished this past Tuesday. When I got finished the stub seemed a little short, 5'11". Does this mean the antenna is a little long?. The stub is still straight. I got the SWR down to 1.2:1, I think I am going to leave it there. I built the ANTENNASCOPE but I am unsure whether it is telling me the antenna is inductive or capacitive at this point. Oh well I will set up a little groundplane antenna on 10 or 15 that I know is too long and see how it reacts.

4413. Use of lattice line to feed dipole

I have just strung a dipole of length of about 110 feet between a tree and my house chimney. The primary use of the antenna will be 80 and 40 meters, with occasional use on the bands between 40 and 10 meters. My junk box contains a reel of open wire feeder (#16 solid copper wires with 1 inch white plastic spacers spaced about every 5 inches), which would run from my Johnson KW Matchbox to the dipole's center insulator.

I have never used this type of feed line before, and in fact I believe its intended use was as a low-loss feed for TV. I am wondering if I could eliminate a fair amount of aggravation for myself by using a newer poly-coated window-type ladder line with #14 stranded copper-clad conductors for the feeder. Can this type of feeder handle high power? For skimpy specs on the ladder-line feed see

Go with the junk box stuff. It will have lower losses - especially
when it is wet. A much better choice.

Well this is where I am comming from, I am presently building an
antenna for this winter where I will be communicating with the U.K.
Thus my major lobe needs to be robust between about 10 degtrees and 4
degrees to ensnare most of the communication. Notwithstanding that the
upper half of the major lobe serves no usefull purpose to what the
antenna is required for there is a mass of radiation in many directions
and levels that have no connection to the required purpose of the
antenna, thus we have a lot of wasted radiation that if we harness it
so that it is used for the antennas primary use the efficiency of the
antenna would increase immensly. So to the question, accepting that the
major lobe is required in its entirety for the antennas required use I
feel that less than 50% of available radiation is used for the antennas
design usage and that also includes the upper lobe as not being a
positive contributor
However I have no real figures to hang my hat on..... O.K.?

Hmmmmm I would question your logic on that figure. since I am not aware
of the normal ratio between actual resistance versus radiation
resistance which would point to
the manufacture of radiation energy relative to the total energy input
however my question relates to the efficient radiation to the
requirement at hand

Hi Art,

The classic solution is to stack yagis vertically. This draws down
the higher radiation lobes and puts their gain in the forward
direction.

However, unless you can positively insure that higher radiation does
not actually find its way to the target (you need a propagation
modeler to prove that, by the way), then you could be muffling
yourself at one elevation to yell at another elevation that is only
heard in points remote from the target.

In other words, if you suppress the lobe at 20 degrees to optimize the
lobe at 10 degrees, you may miss your target altogether. Given that
skip works on so many variables, an "efficient" antenna may be wholly
useless.

Since you mentioned San Diego, let's add the following: The SOBARS club has two nets on Tuesday evenings, one 10m (SSB simplex) and one 2m (FM repeater). There really is a lot of hamming taking place. When the repeater craps out (rarely), we all switch smartly to simplex on the output and carry on, including relaying for stations that can't hear it all. Most of the talk is ham-related, with an occasional what-i-did-on-my-summer-vacation" thrown in. Antennas get their fair share of the chatter.

Well you are getting closer to the question at hand. You have now
doubled the
power input but only slightly gained directionality(2db) efficiency I
would also suspect that you have flattened the lower lobe only into a
pancake shape. But again I go back to the desirable radiation which can
be said in this case to be the lower half of the major lobes half power
envelope which for a directional radiated array is very small compared
to the total radiated field.True propagation can play games but the
ARRL
give the average arrival angles over a 11 year period so it is not a
hopeless task to get a ball park figure regarding usefull radiation
knowing where the target is
I suppose I could make a model and slice out the half power lobe
portion and compare the two volumes for myself, I just thought that it
had already been looked at
Oh well back to the drawing board

Art, from Wikipedia and me, some definition that might help you express your problem in conventional terms:

Directivity is a property of the radiation pattern produced by an antenna. It is defined as the ratio of the power radiated in a given direction to the average of the power radiated in all directions.

Gain is the product of the efficiency of the antenna and the directivity.

Efficiency is the ratio of total power radiated to power into the antenna.

Efficiency of practical Yagis is very high as Tom has told you. Loaded / trapped Yagis are not so efficient due partly to losses in the loading coils / traps. This is the same issue that commonly arises with shortened antennas.

It is quite wrong to say in general "that the yagi is very inefficient".

You seem to be talking HF, the azimuth beamwidth of most practical HF Yagis is so large that you are unlikely to notice much difference in gain within 3 deg of boresight, so on a fixed heading you would expect to cover the 10 deg to 4 deg target area comfortably with little variation in gain.

If you want to maximise the transmitted signal for that specific path, you should minimise losses (eg avoid lossy traps and coils, feed system losses etc), increase directivity (more elements, better design), pay attention to the desired path elevation (eg mounting height of the antenna).

Hi Art,

It is instructive for others to consider, so I shall proceed with very few of those variables considered (we can see you offer nothing in the way of time of year, time of day, frequency, Sun spot count, and so on):

20M 0000 UT Spring 5-7 deg

20M 0000 UT Summer 4 deg

20M 0000 UT Fall 6-8 deg

20M 0000 UT Winter 7 deg

20M 1200 UT Spring 3 deg

20M 1200 UT Summer 2-10 deg (depending)

20M 1200 UT Fall 2-3 deg

20M 1200 UT Winter 4-6 deg

40M 0000 UT Spring >10 deg

40M 0000 UT Summer 8-12 deg

40M 0000 UT Fall 3-12 deg (depending)

40M 0000 UT Winter 3 deg

The numbers above say absolutely nothing about the probability of making a contact.

If you stacked 4 to 8 yagis as high as 4 wavelengths, you might find something "efficient."

I think the parameter that you are searching for is GAIN !!!!

An antenna only has gain by compressing power more into one direction more
than another. It is a case of robbing Peter to pay Paul, the more power you
have in the main lobe the less you have in other directions.

I'm not sure I understand the question, but a large fraction of the total power is typically in the main lobe of a Yagi. You won't increase the power in the main lobe significantly by reducing or eliminating other lobes, because there just isn't much power there. If you want more power in a narrower range of directions, you need more directionality, which means a longer Yagi, stacked Yagis, or some other type of antenna which will probably be larger. The methodology for and tradeoffs involved in increasing directionality are well known. And because Yagis (ones not having lossy traps or loading components) are very efficient, directionality and gain are inextricably linked.

It occurs to me that by art's definition, all antennas are "inefficient". When you're talking with someone, only a teeny, tiny fraction of the radiated power is going precisely in the right direction to be collected by his antenna, so the remainder is wasted. Shucks, I'd be amazed if the "efficiency" of the best HF antenna is better than 0.001% by this criterion.

The other point I note is that he wants enhanced HF radiation between 10 and 4 degrees elevation and apparently beamed to a specific point on the globe... The cubic size and the towers and the arrays that it will take to accomplish this are not efficient in time, money, and effort... He is chasing a unicorn...
As has been pointed out already, the percentage of time that the major portion of the arriving HF EM wave is below 10 degrees can be enumerated on the fingers of one hand... Besides, who is going to have the array on the other end with comparable response?

what you are missing is the variability in that arrival angle. if you are
interested in a specific path you must be able to receive all the possible
arrival angles, which with yagi's requires mounting several of them at
different heights. for instance consider a path from w1 to western europe
at the sunspot peak on 10m... it is not uncommon for the band to open at a
very low angle, say where a single yagi at 120' is the best antenna, then as

the day progresses the angle increases so much that the 120' antenna is almost worthless but one at only 30' is working great. if you put everything into getting that 10-12 degree angle you lose out by mid morning when the arrival angle is up to 30 degrees or more... but at the same time that top antenna may be working great into siberia!

what you are looking for is not normally called 'efficiency', but 'directivity'. unfortunately horizontally polarized yagi's vertical radiation pattern is very dependent on height and the terrain so increasing the directivity is seen mostly in the width of the pattern. and as noted above, controlling the vertical pattern is normally done by changing the antenna height, usually by stacking multiple antennas on the tower and selecting them one at a time or in combinations to give the desired vertical coverage. There have been some experiments with variable phasing of stacked yagis, but it is not a common capability in amateur installations.

Gentlemen let me reiterate
I am building an antenna for this winter and my target is the UK Thus
I submit that the main lobe is the area of radiation contact and which
comprises of a certain volume (and I am looking for a ball park
figure)
compared to the radiation emmitted from the whole array.
What is so wrong with that question,? It seems that people are avoiding
the main question and diverging into other areas for the sake of an
augument
There is nothing wrong in not knowing the answer and you do not have to
post
or respond but you can always start a new post where a facet of your
choice
can be discussed

Right on Jeff
Obviously I would like to rob Peter of everything he
stole and give it to Paul because he is doing something constructive
with his energy where as Peter is robbing energy and just throwing it
away
If Paul had posession of that energy then his half power beam width
would
increase as opposed to decreasing in the pursuit of gain using the
small amount
of radiation available to him

Denny,

This is all apparently intended as a guessing game, as art has given us just one single parameter of the exercise --- he wants to communicate with the UK in the winter.

From where?

At what time(s) of day?

On what QRG(s)?

What construction constraints? (budget, zoning, etc.)

Close but No CIGAR!

Yep! Build the hotel. Sell it to Donald Trump. Buy an Island in the subtropical Pacific.

Move to the Island.

Then do whatever you want for antennas, power levels, exposure limits, get a good QSL Manager who will never bother you, etc.

But, leave some time for fishing, bikini watching, and brew enjoying. If you plan it correctly you can get a VERY RARE KH8 license ...

Hmmm ... I don't like pile ups. Oh well!

Concure. Plus it will have a MUCH lower wind resistance. My window type
feeders with copperweld wire break about once a year due to wind
whipping. Good choice!

Hi Roy,

Not far off.

If absolutely EVERYONE (presuming 6 billion of us) on the planet got
art's signal at S9 from a 100W transmission, that would only be 300 mW
captured (0.3% efficient).

I suppose the 99.7W lost would contribute to Intergalactic Warming
(which would be 99.7% efficient). However, HF temperature is for all
practicable purposes indistinguishable from absolute Zero.

4443. Directional antena and beacon for robot guidance

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-22 18:09:52 UTC
From: G_dir <gbrunello@gmail.com>
Message-ID: <1158948592.570035.301690@m7g2000cwm.googlegroups.com>
Source record: 52430

Hey,

I am building a robot for a competition (simple drag race on a dirt road during a canadian winter).

I wanted to use a beacon transmitting in the RF range, and use a directional antenna to correct the angle that the robot is travelling. The robot would then travel forward towards the beacon (placed at the end gate). So far I have no antenna experiance (havent taken the antenna class yet).

Would a circular antenna work for this project? where can i learn more about circular antennas?

Also are there any commercial (inexpensive, the competition only allows a $100 budget), tranceivers I could use (preferably in the 433 Mhz band). Since i only need a small signal to correct the course, it doesnt have to be too powerful.

Thank you for your help,

G_dir

> when the arrival angle is up to 30 degrees or more...

David that is not absolutely correct, we are talking about a single
point to point communication where the arrival angle is below 10
degrees. If the angle of arrival is above that then it is created by
unusual propagation or deflection of radiation path. For a given
distance one can say that the communication energy level is comensurate
with the number of skips taken where a point is reached when the number
of skips controls the amount of energy left at the communication
distance. Thus the east may hear the west coast talking to Europe where
they cannot hear the transmitting station because of the excessive
number of hops. Remember, I am talking about point to point
communication
which largely defined by the number of skips taken which is why dipole
to dipole transmissions are pushed aside for those desiring DX contacts
tho I am sure you are not advocating dipoles for DX.

but at the same time
> that top antenna may be working great into siberia!

No... stacking is used purely to provide a vector to combat the earths
magnetic field
which affects all radiation directional patterns not only a vertical
pattern

There have been some experiments with variable phasing of stacked
> yagis, but it is not a common capability in amateur installations.

Exactly since these methods provide a vectoir to counteract the
terrains magnetic field
unfortunately this requires extra power supply points where the desire
is for just one.

Roy you know better than that ! gain is a binomial function with
respect
to the forward radiation at the point of initiation. It does nothing to
salvalge energy
expended in the reaward direction, to do that another vector is
required that cannot be produced by a planar array. As far as traps
being lossy as if they get hot or something that is also untrue, what
you are seeing is a radiation field created by the trap that is in
opposition to that created on the element i.e. a field that is 180
degrees out of phase

If you want more

The light beam idea is different but it does bring complications
For drag race you haven't got time to focus a light upon a small object
that is moving
Fior this purpose it would seem that a small verticle would suffice
such that the vehicle responds immediatly to commands I assume that as
a drag race range power is not a requirement. Richard was your aproach
based on a guided path control by light rays such that contact would
provide a direction correcting command?

Egad. There's no point in my wasting time by attempting to contribute
further to this. I'll leave you to your alternate reality.

Hi art,

If time is of the essence, it is of the essence for all applications
equally.

>Fior this purpose it would seem that a small verticle would suffice
>such that the vehicle responds immediatly to commands I assume that as
>a drag race range power is not a requirement.

A vertical has no way to discriminate falling out of a path. UNLESS:

The aeronautical system of holding a flight path is with (or was with)
VOR. It's been a long time since I've maintained navigational
equipment, so my terminology may be way off. However, the concept is
there are two transmitters sending an Morse N and a Morse A, such that
if you are on the flight path, you obtain a constant carrier (the dits
and dahs overlap through carefully balanced antenna arrangement at the
transmitter).

If you should diverge from the flight path, there is an imbalance in
signal and one code predominates over the other. For the race car,
the burden would be on translating which code dominates, and what
course correction would be necessary.

>Richard was your aproach
>based on a guided path control by light rays such that contact would
>provide a direction correcting command?

A light path can be resolved with hardware logic instead of software.
Faster performance.

Yes I am aware of that but not for a flight path but for a destination
point
As a Londoner during the war, the big one that is. civilians were
constanly aware
that light emmissions allowed for night bombing but even when we got
rid of glass windows and replaced it with tar paper the dock area was
repeatedly pounded. Fortunately a bomber crashed somewhat intact and
the secret was opened. The germans had two widely separate transmitting
stations one with a continuos dot and another with a continuous dash
and where both transmissions was aimed at a required venue thus the
german bombers mnew when they were over the target when the dots and
dashes merged into a single drone. In relaliation british fighters were
able to anticape their arrival and finally drove them out from the
skies. My family house was knocked out in the early days when it was
like a carpet bombing but as time went on the raids became more
scattered and without the normal prewarningThe germans did not know
that their secret was broken so the British put out a rumour that their
pilots ate lots and lots of carrots which had ingredients that improved

night vision thus the german fighters obtained this addiction to
carrots. Unfortunately the battle continued later with the doodle bug
that I counted as they went over and then a short period of V2s
that fairly quickly stopped as the Allies advanced in France and
Belgium. Sort of something like the Yagi invention which was not
followed up by the Japanese military
because of inter secrecy of the invention between the services. On the
other side of the coin tho the british invented the jet engine it was
the germans who took advantage of it first with the jet fighter but
internal wrangling delayed its inaugeration. It all goes to show that
people reject change even tho it is inevitable and thus account for the
present resistance to the yagi being inefficient because most feel that
is the cat's wiskers and it takes a generation for change to take place

Cecil as I said in another posting it takes a generation for change
to be accepted. Until then the common response is I don't understand
because their education followed a well trodden path where memory was
the accepted
path to success. Unfortunately this allowed things outside the trodden
path to be bypassed as the great unknown. Note that Roy did not give a
sensible response only theatrics to either of the things I pointed out
because conflict often prevents reasonable thought with an open mind.
If theire was no conflict in his mind he would have trotted out how the
radiation to the front is enhanced by radiation to the rear that is if
he had the answer.......but he does not . As far as reflections go that
was not part of his education itiniary so he will go with the flow. Roy
is an expert in his particular field because he has a good memory take
him outside that boundary and he becomes a different person and pouts
Fortunately he said he is not going to bother me any more so that it is
my hand
hand ithat is lifted .Shame that Reg is not around to witness his feux

Yes, someone does. It was pointed out quite clearly that ALL the gain
from sidelobe or back lobe could not be assembled into very much
constructive gain. Economists call this the law of diminishing
return.

>A casual look at a yagi radiation pattern would suggest
>that it is less than 50% efficient at best

Is false. One can certainly contrive for abysmal efficiency (you use
mylar and bamboo in place of tubing don't you?); but that does not
make the range of yagis fall into disrepute through aberrations of one
designer.

>especially when considering

Is false - there are no externalities, except local ground loss, to an

>an
>average amateur antennah

You don't have any choice in the matter. No element pair is ever
going to offer better. No single yagi is going to draw the peak
launch angle down to the elevations I've already identified. A stack
of yagis is hardly likely either.

The long and short of it is that you are facing 0.001% "efficiency"
without any probable method to even budge it up to 0.0015%.

Creationist scienze might help tho'.

No, whatever art's problems are, I don't believe he's a troll. I'm confident that he's sincere in his statements and questions. It's just that he often makes no sense to me, and when he does, it's sometimes so contrary to established physics that it's reminiscent of the new age folks. His unconventional use of "efficiency" is typical, like the use of "energy" by the paraphysical crowd. Once in a while I make an honest try to contribute something rational, but usually end up just making him mad and provoking even sillier statements -- as happened again this time. So there's really no point in it.

Ok, I reread the original post, and it is right here.

The problem is that you need to understand that the angular center of
the main lobe is dependant on the height of the beam above the ground,
so this part -

> where the main lobe itself is centered between 13 and 14 degrees with
> an
> average amateur antennah

is actually a variable.

Here lies your problem.

No element pair etc pretty specific statement which offers safety

No single yagi is going to draw the peak .....
But you are sticking with the inefficient Yagi, that should make it a safe statement
I would listen more intently if you stated that the angle cannot be drawn down regardless of the array used

> launch angle down to the elevations I've already identified. A stack
> of yagis is hardly likely either.

Hi Art,

Safety? The world recognizes a dry comment that is factual and does not attach notions of sensation to it. [Fair warning to the alliteration intolerant.] Fantasy fear (from prophecies) is called the Pathetic Fallacy.

>I would listen more intently if you stated that the angle cannot be
>drawn down regardless of the array used

Another fallacy. Art, no one believes you would.... aw let's just test the hypothesis to expose another fallacy:

The angle cannot be drawn down to those needed regardless of the array used. You haven't got a chance at all. You are fated to cower forever as being "inefficient" without any brighter prospects ever.

>Do you also agree with what Roy said in a senior moment about wasted
>yagi energy?

He wasted a lot of energy on you, Old Man, didn't he?

Still frightened? They say if you talk about your nightmares, they will go away. I heard that last night in a movie "This Gun For Hire" as told by Raven (Alan Ladd) to Veronica Lake. [This thread needs a modicum of real entertainment value now that all technical content has been drained.]

An excellent article. It appears to indicate that at 7 MHz a feed line made
from 100' of Wireman 554 window line would have a loss of about 2 db when
the line is wet. When the line is dry, the loss is insignificant.

I've often wondered how someone "wets" a vertical feedline
without using soap.

Is that the matched line loss you are talking about.

These lines aren't always or even often operated at very low VSWR, so
it may be unwise to dismiss the loss as insignificant in the general
sense.

I completely agree. If you want to filter out the less serious, then
use a relevant method. Here in Canada, in order to get a no-code
licence, you must get at least 80% on the technical. And technical
prowess will always be important regardless of the mode of
communication.

I see the gain figures on that beauty and I puzzle over why the dBd and dBi gain figures are so far apart -- about 7 db. I expect a difference somewhere in the 2 - 3 dB range. IIRC it's 2.2 dB. What am I missing?

Before I sent this, I did a Google search using some of these terms and discovered "ground reflection gain," a term I have never seen before, except in connection with EME with the moon near the horizon. Is this a realizable gain or damnable inflation of gain numbers?

TKS.

I don't do anything. Ever heard of Oregon mist?

When I first moved up here on the northern California coast I put up a
doublet feeding it with window line. The next spring when I dropped
the antenna for some maintenance I found moss growing on the feed
line.Need I say it was replaced with something better?

Yep. Put a 1/2-wave dipole 1/2-wavelength over sea water and compare
its gain to the gain to a isotropic in free space.

"Stuff happens."

BTW, this "Jawod" signed a message on rec.radio.amateur.homebrew
as "AB8O." I found a blank on that call sign at QRZ.

> >Yes it's obsolete. Yes, it's fun.
>
> I found it to be cold and impersonal.

I agree. Manual radiotelegraphy has NONE of the body language
or tone of voice or much of anything that is normal in everyday
person-to-person contacts. Using this monotonic form of
very early radio allows any user to be anything they want with
no real references to anything but the ability to send telegraphy.

I'd say "clog" as in cholesterol clogging those "hearts."

"Jawod" uses "many" AS IF it were quantitative. Not so much
in the USA now. The US Technician class licensees now
number about 49% of all, twice as large a number as the
General class. I doubt they want to hear such facts.

> >Will CW's elimination be the end of ham radio? Of course not.

>
> I totally agree.

In the USA the number of newcomers is not able to keep pace
with the expirations of licensees. That trend has been evident
for more than a year. [see www.hamdata.com] The majority of
new licensees are Technician class. Novice class, the
supposed traditional "beginner" license has been expiring at a
steady rate for years before the US changes in 2000.

"Jawod" and other morsemen think that all will "like" what they
like. They really don't understand what other citizens want.

That sounds fair. In general I've approved what Industry Canada
does on communications regulations...a bit more than what the
FCC does for US civil radio services.

Source record: 52465

Dear Neighbor Denny:

1. One may have reasonably smooth HF radiation between 4 and 10 degrees with a yagi that is a little over two WL (2.2) above ground (with a maximum of about 7 degrees). The second null will be in the neighborhood of 14 degrees.

2. Many "DXers" exist who have antennas that even at 14 MHz are two WL high. Money-efficiency is very much an individual thing.

3. Many years of dealing with arrival angles of HF signals from over 7 Mm away suggests that such angles are mostly smaller than ten degrees. Larger than 12 or 13 and smaller than about 2 degrees is unusual. With truly serious antennas on both ends, as you have suggested, one might see 1 to 4 degrees.

4. Great to know that we are both still alive. It has been a long time since we have talked.

You probably should read the article yourself, but Table 1 of the article contains columns for matched line db attenuation per 100 feet for dry and wet lines. This set of data is from measurements made at 50 MHz. Since attenuation scales as the square root of frequency, I came up with a rough estimate for loss at 7 MHz. The author then goes on and uses modeling to predict some surprisingly large line losses for the G5RV antenna at 1.9 MHz.

4482. Adapting a 132-foot loop for 80M

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-23 05:09:51 UTC
From: Tom Coates <tecoatesHatesSpam@comcast.net>
Message-ID: <ld6dnaZnTa-2X4nYnZ2dnUVZ_vqdnZ2d@comcast.com>
Source record: 52469

I'm helping a new General get on the air. Your comments on our antenna plans would be helpful. He's renovating a three-story city home with a flat roof. The roof is 16 feet wide and 50 feet deep and about 30 feet above ground. The house is on one of the highest spots in the city and the horizon is visible in three directions.

We're considering a 132-foot horizontal loop for 40 and higher frequencies, supported by 8-foot 2x2s and fed via a 1:1 balun, RG-8X and an MFJ 949E tuner in the shack about 20 feet below. If the loop was fed with balanced line, would it be usable on 80, or would it be necessary to open it at the midpoint to create an 80-meter dipole?

If a dipole is necessary for 80 would a balanced stub (1/4 wave on 80, shorted at the far end) across the dipole insulator be the best method of switching between a dipole on 80 and a loop on the higher frequencies?

We're looking to get going with an antenna that's quick, cheap and simple.

Comments would be appreciated.

A widely accepted line loss model is that attenuation = k1 * f^0.5 +
k2 * f, your approximation makes k2=0.

>estimate for loss at 7 MHz. The author then goes on and uses modeling to
>predict some surprisingly large line losses for the G5RV antenna at 1.9 MHz.

Not surprised at all, many of the figures in the article at
http://www.vk1od.net/G5RV/index.htm show the loss in ladder line in a
G5RV feed system. Fig 3 shows that dry ladder line loss is not
insignificant in the general sense, and Fig 8 shows the expected
degradation on "wet line" in that application using Wes'
characterisation.

4484. Multiband Vertcal Antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-23 06:50:02 UTC
From: Deni foxfiveVJC <telegrafiste@tiscali.fr>
Message-ID: <ef2lf2$5ug$1@news.tiscali.fr>
Source record: 52471

Given that I can only have one antenna and it has to be a single vertical, not exceeding 45 feet, I'm seeking advice on the best way to achieve this.

The feed point must be at at ground level and will be 100 Metres away fed with low loss coaxial cable.

I can lay down a good radial system and ground rod at the feed point.

I'd like to use the antenna on all HF bands, or as many as possible from 1.8 MHz up.

My choices seem to be,

1. A commercial HF Multiband antenna eg, HF9V
or
2. A vertical wire supported by a 40'-45' fiberglass pole with an auto ATU at the base, eg SG230.

Q . Which way to go? Naturally I'd like to achieve some low angle radiation on some bands.

I'd appreciate any advice on which would be the most efficient system given my constraints.

Anything else I haven't thought of ?

Resistive conductor loss is proportional to the square root of frequency, because of the relationship between skin depth and frequency. The loss of wet ladder line is almost entirely dielectric loss, not resistive conductor loss. In good dielectrics, loss is directly proportional to frequency. However, water is quite different from a good dielectric and with different loss mechanisms, so I wouldn't hazard a guess as to how it might vary with frequency.

In an experiment I did many years ago with 300 ohm twinlead (http://www.eznec.com/Amateur/Articles/Portable_Feed_Lines.pdf), I found that the loss of wet line was significantly different just after it rained (when the line had presumably accumulated dust) than after it rained for some time.

> . . .

In that model, k1 is attenuation due to conductor resistance, which is proportional to the square root of frequency as long as the conductor thickness is at least several skin depths. K2 is dielectric loss, which is proportional to frequency for good dielectrics. So this model is good for common transmission lines like coax or dry twinlead, at HF and above, but not necessarily valid for loss due to water. I commented more about this in another posting.

Slow Code you're an idiot, because only an idiot would contine to post this sort of crap over and over on multiple groups...

No code licensing has done nothing to hurt CW or other license classes, and certainly hasn't turned Ham radio into Children's Band, at least where I live (or have lived over the past 40 years or so)

I don't know where you live, but where I live, the conversations are at least as techincal on 2 meterss as they were before (even 25 years back), and maybe even more so. Given your agenda on polluting the newsgroups (and probably bands too, if you actually do get on the ham bands) with this crap that supposes than anyone that doesn't do 20+wpm code is not a ham, or other similar pretenses, I doubt if you actually are even active on the bands... (bigots rarely are, in my experience).

Yep, we talk about a lot of very technical topics, not the least of which occur on 2 meters, and on local nets, or offline on other frequencies during the day (and heave3n forbid, we actually use telephones too!, and with others outside of our area. The future of ham radio in the Hawaiian islands is likely to be relatively bright, even without an increase in CW. CW is not only the slowest method of communicating, it also is the oldest. Why don't you look into some of the relatively recent advances in the hobby, which most of us have at least evaluated and determined whether we wish to participate, rather than the continual baiting and other crap you post on the groups?

By the way, I can't recall seeing you post an actual call sign, just a "slow code" moniker, so how would any of us really know you are one of us anyway? Even if you are, your'e clearly one that should have been outed many years ago.

Despite the feeling I'm doing nothing more than feeding a troll, I feel it's time to see if you're actually real... IF SO, please reply to my email address (not on the groups, you've polluted them enough already) and we can hopefully entertain an intelligent conversation.

Thanks

> its gain to the gain to a isotropic in free space.

Actually, the gain of a horizontal antenna at reasonable height and reasonably low angles is nearly the same over plain ground as it is sea water.

But do what Danny says, and you'll find that a dipole over ground has a gain of around 6 - 8 dBi. While dBi is rigorously defined, "dBd" isn't. Using a common conversion of 0 dBd = 2.15 dBi (the gain of a dipole in free space), you find that a dipole over ground has a gain of about 4 - 6 dBd. At least one major antenna manufacturer quoted the gains of their antennas over ground in "dBd". Naive people assume that it means "compared to a dipole at the same height", while it actually means "compared to a dipole in free space". Gives their antennas an instant 4 - 6 or so dB boost over the competition.

Art:

OK, so I've read all of your posts, and all of the replies, but somehow,
I still don't know where you're trying to work Europe from....

Maybe I'm dense, or can't comprehend the previous posts, but the best
I've been able to find is that you have a 4000 mile path. Still, that
could be quite a number of locations, given a 4000 mile circle around
europe, though it may not really make much difference...

What bands are you trying to use?
Where are you located?
Why are you so concerned about high angle radiation? The vagarities of
multi-hop propagation often provide some really interesing contacts from
high angle radiation...

Please provide actual information, instead of vagarities...

Thanks

Roy, I agree re the wet lines application. A further issue is that of standardisation of the wet line.

Wes' work and yours shows that there is a degradation, but there is uncertainty regarding the scale of degradation, and effects like salt build up in marine locations could be expected to influence results at the start of rainfall and after torrential rainfall for instance.

I do often use TV ribbon for temporary / portable antennas, tuning the antenna by adjusting the feedline length. I tend to avoid ground dependent antennas for this purpose, and a dipole with TV ribbon has some advantages, but as you note in your article, and as we have all observed, the "tuning" changes with rainfall more than would be observed with a coax feedline.

Since your article was published, RG6 has become popular for TV feedline, and is cheap as chips. It performs very well, and I find myself using it for portable antennas. RG6 is a little heavier than RG58C/U (~30%), a little thicker, but has relatively low loss, approaching that of RG213 as a dipole feedline.

I wonder if anyone has every critically appraised various forms of RG6 for through braid leakage and IMD? I know there is variability in quality, some seem to not locate the centre conductor in the true centre of the dielectric, and aluminium wire braid can be a disadvantage for solder-ability. (Cecil will correct the spelling if you don't know what I mean!)

Hi Alison,

Yes, I already admitted the term was probably pulled from an alphabet soup of navigational equipment I've calibrated: TACAN, VOR, DME, ADF, LORAN (although more commonly marine application) and on and on. The mechanical phasing systems were a workable kludge. But what kludges nonetheless. I've even navigated by the time differential between the Naval Observatory encoded signal in LORAN stations and my atomic clock aboard a sub tender (our LORAN was broke).

>you decirbe the AN corridor scheme.

Which is eminently suited to the problem.

>AN has 180degree ambiguity

Which is not an issue for the stated problem.

>>A light path can be resolved with hardware logic instead of software.
>>Faster performance.
>
>Optical interferometry.

Hardly. This is gilding the Lily and painting the Rose. The optical analog of the AN system is sufficient to the problem. Simpler beacon methods would prevail even here.

The difficult issue is one of a closed feedback loop and maintaining stability, not deciding if one is on or off the path. That is dirt simple. What you DO with the information is the logical nightmare, because errors compound quickly and information descends into statistical nonsense in its out of phase application.

In a recent robotic car rally, the big name universities and corporations with million dollar budgets, gizmos galore (multiple GPS, radar, and what have you) and plenty of engineering talent were literally blown off the road by an insurance broker who hobby funded a garage crew outfit.

BOTH!!

Ground reflections CAN add to the 'freespace' gain at certain antenna heights and angles of incidence. The ground reflected wave is is phase with the incident wave.

'damnable inflation' ... well if one manufacturer uses the term in it's marketing literature then the competitors will follow. Then 'gain' comparisons go to H..L!

The best comparison is free space gain [calculated] as dBi or dBd.

I used to mamange a microwave antenna test range. Out antennas were installed between 20 to 30 wavelengths above ground to reduce 'ground effect confusion'.

Hi Roy,

Some time before Wes's article was published I tried to measure the
stuff myself. I used an eighty foot length of the so call "450-ohm"
window line. My problem was that I really didn't have very good
equipment for making the measurements. I use both a MHJ-259B and an
Autek RF-1. I took several measurements and plotted the results
getting a relatively good scattering patterns and went with that. The
line I used was brand new and clean. For wetting I sprayed the line
using a fog nozzle which makes a good fine mist that "stuck" well.
(Being a damp area I don't have the drying problems Wes has in Tucson)
As best as I could determine the wet losses were about double those
for the dry line. But, as I said my equipment was ham-grade at best so
I sure wouldn't bet the farm on my findings. (Interestingly, I did
measure the dry line's impedance at 408-ohms which matched Wes's
findings right to the ohm.)

AsI mentioned earlier post, I tried using window line here on the
northern coast and found that after being up for about a year I had
moss starting to grow on the line. Now that certainly is going to
crank up the losses!

The bottom line is I gave up using the stuff and, for my tuned fed
applications I use open line.

Deni!

How about a vertical Zepp. It does not need any counterpoise.
I did some experiments with this type of antenna. You will
find it as a 'no counterpoise antenna' via Google. It consists
of a parallel wire and on one of the two wires an extended
wire is connected.

X====================--

The drawing is horizontal, but use it as a vertical antenna! At the
point
X a Balun converts from symetrical to coax - or direct into an ATU.
The Balun is a red core with a 5 turns RG-174 wound twice.
Look here http://home.datacomm.ch/hb9abx/mws.htm

I use a version on a 12m fiber glass and it gave very good results.

Drop me a line if you need more info, email: oe1mww(at)qsl.net

Hi, I have used a simular setup as nr 2. I use a Chinese CG-2000 automatic tuner and it works OK on all HF bands. Gives you alot of options on how to attach your wire. I have used glassfiber rods and also tried a more LW like slanting of the wire. Can really be a flexible antenna. It's not as complex as commercial multiband antennas.

It's critical to have a good RF ground but I live close to a lake so no problem with the radials.....

Go for nr 2....

I'm wondering if an 80m trap would work - high impedance
on 80m - relatively low impedance on the higher frequencies.

> 2. A vertical wire supported by a 40'-45' fiberglass pole with an auto
> ATU at the base, eg SG230.

If the vertical is much over 5/8WL long, its take-
off-angle is too high for proper operation. 5/8WL
~600/f = 21 feet on 10m. Your 40-45 foot height
would only be good up to about 14.3 MHz unless you
figure out a way to shorten the wire above that
frequency.

Here's another idea using the same space and this
is my present vertical antenna. Make the vertical
21 feet long and locate its top at 42 feet. The
feedpoint is then 21 feet in the air. Install
elevated radials acting as guy wires at that 21 foot
level along with the SG-230. That will give you pretty
good 40m-10m operation. For reasonable 80m operation,
install a loading coil at the feedpoint, in for 80m
and shorted for all the other HF bands.

According to EZNEC, on 10m, that antenna has:

*** 4.2 dBi omni gain with a TOA of 11 degrees ***

Rick my call is KB9MZ My antenna which is not of the Yagi design has a TOA of 10 degrees and hopefully will be up before the weather gets to cold. I am restricted in height to 120 feet So as you can see I am pretty well committed to what array I am using. But the initial posting was not about antennas per se but about the efficiency of the Yagi with respect to desired radiation. Some would have you believe that radiation
which is not within the main lobe is miniscual so I suggest you imagine two models one of which has all lobes removed except the main lobe Do you feel that both models now need to be labelled to avoid confusion as they look so much alike?. As for other side comments regarding TOA I suggest one reads the post from Mac which I whole heartedly agree with (Thanks Mac, tried to get in touch with you a few months ago but E mail was rejected)

Wow, from 0.2 dB to 0.4 dB. :-) Would the following
work for measuring the wet/dry losses of 1/2 wavelength
of ladder-line shorted at one end and an MFJ-259B on the
other end? Measure the resonant purely resistive impedance
at the open end. Wet the ladder-line and repeat the
procedure. Calculate the losses.

If the line were lossless, zero ohms would be read.
The deviation away from zero ohms yields the magnitude
of the loss in the line at the 1/2 wavelength resonant
frequency. That's about 8.8 MHz for 50 ft. of ladder-line.

You are assuming something that I am not. That is the measurements
were accurate. Measuring anything to a fraction of a dB is most
difficult - even with the best of equipment and mine was not.

It is a long time since I completed the Oxford and Cambridge entrance
exam on written english so I probably have lost some of my style
because of my under pinninings of being a Cockney It took a while
working in America to obtain communication skills but not long ago
while in San Diego I came across the college for American spoken
english
which I was unaware of. However because of a broken brain which is the
result of a heart attack it is too late for corrective action.
Fortunately I have no difficulty in the
comprehension of the main style american language which allows for a
modicom of understanding

> figure out a way to shorten the wire above that
> frequency.

Just to note that the peak field _generated_ by a ground-mounted
vertical up to 5/8 wavelength high always occurs in the horizontal
plane. Ground losses for the displacement currents in the earth
gathered by a buried radial network within about 1/2 wavelength
of the antenna will reduce this field from its theoretical maximum
value, but peak relative gain _as radiated_ always will remain
directed in the horizontal plane, regardless of the amount of
those ground losses.

Calculating the "pattern" of a vertical radiator at an infinite
distance from a site on the earth leads one to think that the
radiator produces zero field in the horizontal plane, and that
its maximum field _as it is radiated_ occurs at some higher angle.

But this effect is only due to groundwave propagation losses
related to earth conductivity, the r-f frequency, and earth curvature.
It doesn't mean that the vertical radiator originally produced
zero h-plane field -- just that the higher angle fields were the only
ones to survive the trip to an infinite distance.

If the above was not true, MW commercial broadcast stations
would have essentially no daytime groundwave coverage.
Their nighttime, distant skywave coverage also would be affected,
because much of that is produced by elevation plane radiation
between zero and +10 degrees.

So is the lesson that Ladder line sucks, or is it that we shouldn't
wash our ladder line with soap and water? 8^)

Has anyone run tests on what "real" (open) ladder line does when you
spray it with wetting agent and water?

That's pretty amazing. East Texas is relatively damp
and green but I've never had moss growing on my ladder-
line. Here, the rain comes and goes and doesn't last very
long.

> What do you suppose the dielectic properties are when that stuff
> totally bridges the line and is wet?

Sounds like a useful project for someone. The only thing on
my ladder-line at the moment is a green six-inch long lizard
looking at me through the window pane.

Some suggest coating the ladder line with various forms of waxes, eg
silicon car polish for various reasons, including minimising the
change to the line characteristics with precipitation.

I don't know if there is reliable evidence as to the efficacy of these
measures, and what compounds are to be preferred. I see it discussed
on eham, but that doesn't necessarily mean it is bunk!

I don't know that it is fair to say that "Ladder line sucks", but it
is well known that it is adversely affected by moisture. Ladder line
is not so good wet or dry as to disregard its losses in all situations
(ie in general).

Like everything, it has its limitations, and with knowledge we can use
it effectively within those limitations.

Owen

Seems as if some of us are taking special circumstances and applying
them to all cases. I have the same type of line, and after several
years, it's still glossy, and the water beads up on it.

So should I quit using it because he has problems, or should he keep
using it because I don't? ;^)

Hi Owen.

I doubt that those would help much, as PE has some pretty impressive
characteristics. I suspect that waxes and such will just degrade
performance.

And I can just imagine the look my XYL would give me if I told her I
was going to go wax my line! ;^)

I wonder what the exact mechanism is? PE has some decent water
absorption characteristics, 24 hour tests show almost no absorption for
low density, and none for the high density and up versions.

I have a spray can of NAPA MAC'S Silicone spray. It says:
"Waterproofs and Insulates". I've got a thunderstorm on
the way and just sprayed about 2 feet of my 450 ohm ladder-
line with it. I'll see if I can tell where the silicone
spray is and if it has any visible effect on the water.

Sask. ham radio operator speaks with space station
http://www.canada.com/nationalpost/news/story.html

Published: Saturday, September 23, 2006

SASKATOON - Ned Carroll's amateur radio has connected him with people all over the globe, but now it's given him an experience that's out of this world.

Mr. Carroll spoke on Thursday with Anousheh Ansari, an Iranian-American space tourist aboard the International Space Station (ISS).

The small radio inside Mr. Carroll's farmhouse, west of Davidson, Sask., was tuned to the space station's frequency and picked up its signal at around noon. He heard a slightly accented woman's voice coming through the speakers of his ham radio.

"I heard her say, 'C-Q, C-Q, C-Q,' and of course that means she wants to talk to someone, anyone who is listening," Mr. Carroll said. "And I thought: What the heck, you can't lose by trying."

He rushed over to his radio, grabbed the microphone and said, "V-E-5-N-E-D," his call sign, and anxiously awaited a response. He didn't have to wait long, as the voice responded immediately, repeating, "This is R-S-0-I-S-F," which is the Russian Space Station call sign, and then the voice revealed her name, "Anousheh Ansari."

When Ms. Ansari, co-founder and chairwoman of Prodea System, Inc., lifted off on the Soyuz TMA-9 mission from the Baikonur Cosmodrome in Kazakhstan on Sept. 18, she became the fourth, and first female, space tourist. She reportedly paid US$20-million for an eight-day visit aboard the ISS and was already trying to make contact with Earth.

"I was pretty excited," Mr. Carroll said. "And the next thing I was so excited about was when she said, 'You are the first amateur radio operator that I have contacted from the International Space Station,' and I said, 'Wow!' "

There are thousands of ham radio operators worldwide, but Mr. Carroll is one of a small number of people who have made contact with the space station, said Bjarne Madsen, midwest regional director of Radio Amateurs of Canada.

"It's quite rare," Mr. Madsen said. "There are a great
many people who want to [make contact with the ISS] and
only a few that succeed because there is, after all,
only one ISS and it's only there for a few minutes at
any given time and the opportunity to actually make contact
with it is very slim."

Mr. Madsen said the space station creates a line a few
hundred kilometres wide at best, moving across the Earth
as it orbits. A radio operator who happens to fall within
that line as it passes by, within an eight- to 10-minute
window of opportunity, can communicate with the ISS, he said.

"Not only is it possible to do, but it doesn't take any
sophisticated equipment particularly," Mr. Madsen said.
"It's really a question of knowing where to listen and when to listen."

Within the small window of time, Mr. Carroll said he
and Ms. Ansari were able to give only their locations,
comment on how well they could hear each other and then
exchange goodbyes. Afterwards, he said, many questions
came to his head that he wished he had had time to ask her.
But he said he is going to keep his radio turned on in
the hope of speaking with her again, even though he knows
his chances are slim.

"[Amateur radio] is a wonderful hobby, and every once in
a while something like this comes along and you really enjoy it,"
Mr. Carroll said.

I don't recall seeing suggestion that the mechanism is a change to the
PE due to absorption of water.

The water on the surface of the PE is immersed in the E and H fields,
and is likely to change the RLGC characteristics at a frequency.

I think Wes' work was valuable in demonstrating that the changes are
not lossless, even if it is not practical to estimate the magnitude of
the changes because of uncertainty in the "wet environment" at any
point in time.

So, we know that the changes in loading that we observe with an ATU
are likely to have an increased line loss due to the water. That loss
warrants consideration, a reason to consider other line constructions
in certain environments.

Wes and I discussed inclusion of his "wet" figures in my line loss
calculator at http://www.vk1od.net/tl/tllc.php . Wes' preference was
to not include them, I am happy with that in that you could read too
much into the calculated results because of the lack of standardised
"wetness" in the real world.

I would suspect that any oil or wax compounds would be a tad sticky
and may, over time, accumulate more dust on the surface. That, in
turn, could in be a good rooting medium for moss and/or mildew to
form?

By the way I did spray my ladder line with silicone spray when I
originally put it up.

Aha! I was troubled with how you got mold or moss or anything to stick to PE. I believe you are correct in your suspicions. One of PE's main draws is it's inertness, and it is a real bear trying to get anything to adhere to it. There is some possibility that the spray may have contributed to what appears to be pitting on the line.

Certainly something troubles me with the idea that we can test something under conditions where we apply chemistry to alter a fundamental property of the material. (I'm referring to the wetting agent tests) I believe that the tests do show adequately how ladder line performs when covered with wetting agent and water. And that we don't want to do that! ;^)

Not trying to insult anyone here, Wes. Just trying to figure out what is going on.

And after a little discourse, we find out that Daniel sprayed silicon spray of some sort on the line. That starts to make some sense of why he had a problem with the line.

I'd wager his mold, moss, or mildew problem has more to do with his unapproved use of chemistry on the line.

Well Mike, along my experience with ladder line there is also Roy's
and Wes's measurements. Based upon that, for me, I'm off the stuff.

My present open line setup is appears to be working fine. No
detectable moss, mildew or anything else that I can detect.

One can go on forever trying to justify one way or the other, but thus
far, wet ladder or ribbon line has shown not to be the best route to
go - from three different sources. If you have something to the
contrary I certainly would be interested in hearing about it.

To each his own.

Although I discovered it long ago, I keep getting surprised at how many people require a binary answer to any question -- is it good or bad, sucks or doesn't suck, good or evil. Sure makes it easy for our would-be politicians and their 15 second sound bite solutions to complex issues. Hopefully at least some readers will consider what Owen said, that the knowledge we've gained by this can hopefully help in the intelligent use of the line. Those needing a binary answer should look elsewhere; there are plenty of gurus who are more than happy to categorically state positive but simple answers to just about any question. I use a coin, myself, but each to his own.

Wes' and my measurements, and Danny's observations, can't be directly applied to other situations. What they're meant to, and do, illustrate, is that significant loss *can* occur under some circumstances, and people who assume that twinlead or window line loss will always be low can be very much mistaken.

>
> Has anyone run tests on what "real" (open) ladder line does when you
> spray it with wetting agent and water?

I don't think any result would be very meaningful, except to show, again, that significant loss could occur under some conditions (which I'm confident is the case). Those lines are often run with a very high SWR. The effect of conductivity and/or loss across the insulators would depend very heavily on the position and size of the standing waves. For example, if the SWR is high and the insulators happen to be at or near the voltage peaks, even a small amount of loss would have a major impact. But on a slightly different frequency, the antenna's impedance will change and the standing wave will move. If most insulators are near voltage minima, you wouldn't likely notice even quite a bit of loss. This effect would be most pronounced at higher frequencies where the spacing between insulators might become a sizable fraction of a wavelength, and not so pronounced at lower frequencies or with more insulators. But the magnitude of the SWR would still make a major difference.

How do you suggest that the power that is not in the main lobe is removed?
You either have to somehow concentrate it into the main lobe or dissipate
as heat in a load.
If you concentrate it into the main lobe then the gain of the main lobe will
go up, if you dissipate it as heat then the gain will remain the same. If
either were possible they would not look like the original yagi.

You seem to miss the point that the gain in the main lobe is effectively the
power in the area illuminated by the main lobe divided by the power in all
other directions.

Reduce the power in the sidelobes then the gain must go up, (unless it is
dissipated as heat, which is not possible in a yagi).

Sigh. Guess I'll try one more time.

Suppose that the Yagi has a front/back ratio of only 6 dB, and that the angular span ("height" and "width") of the rear lobe is the same as that of the front lobe.

1. Figure out how much power is contained in the rear lobe compared to the front lobe.

2. Express that ratio in dB.

That's the amount you'd gain by eliminating all the power in the rear lobe, and moving it into the front lobe -- if you can do it without increasing the angular span of the front lobe.

Repeat with a 10 dB front/back ratio or whatever you think your present Yagi has.

Now, that wasn't so hard, was it?

An unconventional definition of the term "gain".

How can there be rational discussion of principles when some people
must invent their own meaning for terms that have well defined
conventional meaning?

I'm sorry, I didn't say what I intended to. What I meant for step 2 was:

2. Assume for a moment that all the power was in a single front lobe. Calculate how much, in dB, that front lobe power would be reduced by putting the fraction in the rear lobe which you calculated in step 1.

It's been a long, long time since I took an amateur exam. But I'd think the ability to make these calculations would be within the reach of anyone who passed the General class exam.

Here in East Texas it rains much less than 1% of the
time. Rain is more often than not accompanied by lightning
during which my antenna is unplugged. Wet ladder-line is
just not a problem at my QTH especially since the only
horizontal portion of the run is under the eaves of my house
sheltered from the rain. The only portion exposed to the rain
is vertical and is usually being whipped dry by the wind.

But what about the water collected on the antenna wire itself?

How about "power", Owen. Some physicists say that a
Poynting vector contains no power until some work
is done - that if an EM wave in free space never
encounters anything to which to transfer its energy,
its ExH watts are not power.

My question is: If an EM wave's ExH watts are not
power, what are those watts called? i.e. the units
of power are watts, but if in some cases, watts are
not power, what are they?

Dear "Jeff" (no call sign):

Please read and study an antenna text such as Kraus' third edition of Antennas. His first edition (published in 1950) is also an excellent reference for this issue. The terms you use have been well defined for many decades. Only patent attorneys are entitled to define word meanings that differ from convention - and then only in a patent application. Words have meanings.

Wow, I made a big post and then lost it. Take two.

I've put up a 12m Spiderbeam pole + wire + base matching networks fed against 27 ground radials ranging from 20 to 40 feet long. I'm using it only on 80m, 60m, 40m, and 30m, and I've been quite happy with it. As Cecil mentioned, it should work quite on 20m as well, but on 17m and up it will have a less than desireable radiation pattern.

I'd still recommend getting the pole and autotuner. I think the overall efficiency will be more related to what you can get in as ground radials than which antenna you use. I think that the cost is probably about the same in both cases. What you get with the 40 foot pole and autotuner approach is a 40 foot pole and an autotuner! Better parts to try out different antennas.

As far as the bands above 17m, two suggestions come to mind.

1) For routine, easy copy communication on 17m and up, just use the antenna as is. It's bad for low angle radiation, but you're not going to notice the differerence when you're hearing s9 signals that could be s9+10dB instead. If good DX that you're having trouble hearing comes on 17m or above, go out, drop the pole a few sections, and reattach the wire to the tuner. Voila, your too-long vertical isn't anymore. Cecil's suggestion to use a 21 foot vertical instead is just fine, but you lose 80m in that case, and at this point in the sunspot cycle, I'd personally take inconvenient operation on 17 over giving up 80m.

2) An old approach using new parts, if you can run a couple of wires out at angles from the top of the pole. Put up an inverted-vee doublet at the top of the 40 foot pole. Make some open-wire line to feed it. On the lower bands, feed both feedline conductors against a good radial system. On the higher bands, feed the doublet as a doublet. I haven't tried this due to the lack of an autotuner, but I think it could work quite well. It doesn't exactly fit your criterion of one 40 to 45 foot vertical, but the visual impact is the same... maybe you've got some trees or could tie things off to the house ... it's a top loaded vertical on the lower bands, and a nice, high inverted vee on the higher bands.

In the middle region, probably 30m and 40m, you could pick whether you were using the doublet or the vertical depending on who you were trying to contact.

As my girlfriend likes to say "WORDS MEAN THINGS!"

Having a weird definition of efficiency doesn't help anyone out.

Needing an antenna with super-high-gain at one particular elevation and azimuth angle is a weird, but... sort of valid question... but has nothing to do with the efficiency of said antenna.

Dan

Cecil's absolutely right about this... but, a suggestion. Right now, above 14MHz, the bands aren't so hot. 17m is open a lot, 15m is open sometimes, 12&10 almost never.

I'm using your setup #2 on 80m, 40m, and 30m and have been quite happy with it. The radial field is 27 radials ranging between about 20 feet and 40 feet (out to the edges of my yard) I'm using one of the 12m Spiderbeam poles. I built my own L-matching networks for the base, just because I didn't have an autotuner. I've noted good DX performance. I don't have any quantitative numbers, but I'd make my recommendation on another basis.

I expect a good multiband vertical costs about the same as a 40 foot telescoping fiberglass pole + decent autotuner. Radial costs are the same...

However, the antenna *versatility* of the pole + autotuner is much better. You get better parts for your money. You will certainly be able to load up a 40 foot vertical on 17m and up for noncritical communication.... when signals are s9, you won't notice that they're not s9+ 10dB. If some really good DX comes on 17 and conditions are marginal, go outside and drop the pole two or three sections and reattach the wire to the tuner! Now you've got a 5/8ths vertical on 17m!

The pole will come in handy for portable and field use; the autotuner can be used to match whatever you want to try out in the back yard, and having a nonconductive fiberglass support is great for experimentation.

Something I thought about trying, and would if I actually had an automatic tuner, is rigging up a short inverted vee doublet at the top of my 40 foot pole. It would be short enough to be only bidirectional on 20m and up. Also install a good radial field for the low bands. Homemade open wire line runs from the doublet at the top down to the ground. On 80, 40, and (maybe) 30m, feed both conductors of the feedline against ground. On 20m and up, feed the doublet as a doublet instead. You just need a couple of relays to perform the switching tasks remotely. This is an old approach to a multiband wire antenna

with good performance on both the low and high bands. A nice pole and automatic tuner just makes it all the easier.

In fact, if you want to save even more money, do the doublet/vertical thing but build one of Cecil's all-open-wire matching networks for the higher bands. Some relays and some ladder line, a pole that costs EUR 80, and a bunch of wire, and you've got a good antenna system.

http://www.qsl.net/w5dxp/notuner.htm

One further thing to recommend the 40 foot telescoping fiberglass pole is that you can make it easily disappear when you want to. Mine stays inside when I'm not operating on the lower bands. Of course, I'm just using it as a vertical; it takes 1 minute to take it outside, clip on the guys, and raise the vertical wire. It would be a little more involved to put up and take down a doublet all the time.

Dan

Hi Dan,

From discussions of years past with the chipster, his novel k2 fractal flyer antenna (heavily constrained with unique parameters) offered the "best" gain at 10 degrees that couldn't be bettered by anyone. He took umbrage when this claim was examined in the modeler ("you can't make a copy of that antenna! I own the rights!"):
http://www.qsl.net/kb7qhc/antenna/fractal/n1ir/k2/index.htm

It turned out that the word "Best" meant -4.63 dBi - which I promptly bettered by more than half a dB (in an unpublished design I call the Foolish fractal Flyer). The chipster also made efficiency claims similar to Art's (that is, using the same corruption of language). It didn't take long to flush that efficiency with the same merits.

The moral of inventing meanings for words is that those meanings have a short shelf life. This kind of thing doesn't even last out a week in the white house press room.

True, true. If only all this word-twisting energy could be harnessed as valid antenna design... the chipster seems to have relegated himself these days to fairly innocuous posts elsewhere regarding staying on the good side of your neighbors' graces by putting up visually low profile antennas... Certainly a change from the f-word antenna wars of old. I was a regular reader of r.r.a.a. in those days... not much of a poster back then, though.

I wonder if a thousand-mile long, five mile high stack of rhombics might meet Art's requirements... of course, at that point you could just run open wire line to any distant receiver. That would be quite efficient, from Art's standpoint.

Dan,
you know quite well what the post that started this thread asked for.
I only added the TOA comments to fill in some body where I was
coming from not for advice on what antenna to build.
People are quibling over the word "efficiency" which I find rather
wierd
especially since I am supposed to be in the company of fellow
engineers.
The subject was antenna radiation patterns and ascertaining the
relative volume of the main lobe which is the reason for an antenna and
comparing it to the total volume of the array which one accepts to
obtain the desirable primary lobe. Oh yes, when we talk of efficiency
one must multiply the ratio by 100 Some may have forgotten that!
Obviously this group comprises of a swarm of tadpoles with a few little
goldfish in a small pond none of which are qualified to be termed
faculty. Now you have something to get your teeth into since you deign
to respond to the initial post This term "I don't understand" is
usually used by student who enter class after late night partying and
it didn't work then either. A dull brain is a dull brain unless one
activates it.
Carry on with a thread of your own choice and quibble amongst
yourselves about what "is" is really meant by use of the word "is" For
what was a very short question this thread has gone amok and is way to
long
Art

Dan,
you know quite well what the post that started this thread asked for.
I only added the TOA comments to fill in some body where I was
coming from not for advice on what antenna to build.
People are quibling over the word "efficiency" which I find rather
wierd
especially since I am supposed to be in the company of fellow
engineers.
The subject was antenna radiation patterns and ascertaining the
relative volume of the main lobe which is the reason for an antenna and
comparing it to the total volume of the array which one accepts to
obtain the desirable primary lobe. Oh yes, when we talk of efficiency
one must multiply the ratio by 100 Some may have forgotten that!
Obviously this group comprises of a swarm of tadpoles with a few little
goldfish in a small pond none of which are qualified to be termed
faculty. Now you have something to get your teeth into since you deign
to respond to the initial post This term "I don't understand" is
usually used by student who enter class after late night partying and
it didn't work then either. A dull brain is a dull brain unless one
activates it.
Carry on with a thread of your own choice and quibble amongst
yourselves about what "is" is really meant by use of the word "is" For
what was a very short question this thread has gone amok and is way to
long

I don't recall you stated which band but I'll assume 20 meters.
Assuming flat terrain (for your Indiana QTH), a single Yagi at 120'
(your maximum possible) would cover these angles best. 140' (or 2
wavelengths high if it is not 20m) would be the optimum heightl to
center your main lobe at 7 degrees.

Two stacked Yagis at 60' and 120' would be better than a single one at
120' or 140' for 4-10 degrees, but obviously this means more work and
expense.

If your terrain is not relatively flat, and if you are lucky to be on a
hill with a gentle slope in the direction of England, the optimum
height will be much less. However you would need to model this using
HFTA in the most recent Antenna Handbook or YT in older editions.

Careful, Mark, we can't say such things due to "threats" against
the pro-coders. :-) They are muy touchy about threats against
Them.

Well, Mark, it is like this: Some of those who have the cool
HOBBY of amateur radio think they are "servicemen" in the
"service of their country" for having that hobby. We can't say
nasty to them because that is not "nice." They rank
themselves as equivalent to soldiers, sailors, and airmen.

They want the ILLUSION that they are doing great and
meritorious SERVICE. Especially the morseketeers. That is
important to them. The illusion, that is. Screw the reality
part of it, that doesn't apply to them (they think).

Never mind that US amateur radio licensee numbers are holding
static with a slight downturn over the past three years. Oldsters
are signing off permanently and newcomers are going in through

the no-code-test Technician class. Most of the latter are STAYING no-code. [General Of The Amateurs Miccolis says otherwise but then he loves cooking the stats to suit his own taste]

As time goes on with the code test gone, the amateur bands WILL change. But, it will be slow since humans are living longer now. Human attrition will, nonetheless, happen. Oldsters don't want to think about that but it is inevitable to all of us. The oldsters want to preserve the illusion that they are still "young," believing in the old, antiquated ways they were impressed with. Why some even believe they are a "service to the country" by having that hobby.

There's no argument with those ancient morseketeers, certainly no "discussion." To them, all must be preserved. [read mummified] Ptui.

Bill,
None of that is really a problem to me.I have multi points to which I
can feed for different patterns depending on the time of the day as
well as option of tilting the array. If I don't get my elmer I will
assume he is not on the air and yes it is twenty meters and I am
located in the couintryside that I understand is the highest between
Chicago and New Orleans and since this is the bread basket of the U.S
the ground loam is excellent. I use 7/8 andrews plus a long length
underground and the tower is hinged in two places
as well as another one for array tilting. I have power gain over a yagi
but I was just curious as to how much more radiation energy was
available to ensnare which Is why I referred to array volume since gain
is really dependant on half power beam width required or one can live
with I once had a 80 foot yagi and with the looseness in my prop pitch
rotor combined with the narrow beam one was never sure if one was
really taking advantage oif gain available. Pretty simple question for
those who know the answer after all you start off with 3 db gain in two
different directions thereffore it would seem to me that a yagi was
only 50% efficient but people are quarrelling about every thing except
the posed question to excuse them selves from real thought. Reg would
have come up with the solution after a bottle of wine after noticing
the english provided by the cue
Regards
Art

Take the integral of the gain of the antenna over the angles in azimuth
and elevation that you consider to define the boundaries of the main
lobe and divide that by the integral of the gain of the antenna over
all angles . You'll need your gain as a function of the angles.

That's the number you're looking for, I suppose. I guess it's a decent
measure of sidelobe suppression... but so is the ratio of the gain of
the main lobe to the gain of the biggest sidelobe.

Dan wrote:
"---of course at that point you could just run open wire line to any distant receiver."

Yes, if it isn`t too distant.

If the 1000-mile open wire line lost 0.1 dB per 100 feet, loss would be 52.8 dB per mile or about 53 thousand db in its entire length, hardly a useable transmission line.

On the other hand, suppose the wavelength were 160 meters. In the first wavelength of a radio signal radiated in free space, you would lose 22 dB. In the second, you would lose an additional 6 dB. Doubling the distance again to a total of 7 wavelengths, or 1120 meters, total space loss would be 34 dB.

At a distance of 2240 meters from the transmitter, the loss is 40 dB which is less that our open wire line would lose in its 1st mile, a shorter distance.

Every mile of wire line extracts the same loss. Very long wire lines become useless without repeaters to boost signal above the noise level. Doubling line-of-sight radio path distance only increases path loss 6dB, no matter how long the path is.

As for efficiency, J.D. Kraus says:
"The efficiency of an antenna is defined as the ratio between the power radiated by it and the power delivered into the antenna." (page 866 of 3rd ed. of "Antennas".

Best regards, Richard Harrison, KB5WZI

You coated your line with something it shouldn't have had on it. The
other line was coated with wetting agent, which some of us might think
was an artificial substance to be coating it with.

We can draw lessons from all this.

> myself, but each to his own.

I ask the questions that I do to find out what might be going on. I've learned a few things here. one is that if you coat PE with some substances, it will alter it's properties.

Another is that there is a measurable difference in loss when a PE line is coated with a wetting agent, which is needed to evenly (read wet) coat PE with water. Some portion of this could be applicable to non-wetted PE coated line.

> Wes' and my measurements, and Danny's observations, can't be directly

I would assume then that the big difference is the continuous coating of
the PE then?

Thanks for the feedback, Roy, I'm here more to learn than to argue.
(perhaps Quixotic?)

Mebbe, Richard. I hate to sound skeptical, but it actually grows on untreated PE? I mean PE's inert behavior and the difficulty of anything sticking to it are one of the reasons that companies like Nalgene (okay, Nalge) use it.

I would think that the definition quoted was more applicable for a
radiator
than a antenna since the latter consists of addative and so called
destructive radiation. If an antennas radiative field was totally
destructive
the definition stated would include that as an efficient antenna !

Hi Art,

A few points below, but first just remember that the TOA of any horizontally polarized antenna is primarily a function of ground reflections which vary according to height above ground. Previously you mentioned that your antenna was designed for a TOA of 10 degrees. That cannot be true except for a specific height above ground. Whether Yagi, Quad, Log, Rhombic or any non-vertically stacked antenna. Something like a Sterba curtain is different because it has multiple elements stacked vertically which CAN be steered by phasing.

art wrote:

> yes it is twenty meters and I am
> located in the couintryside that I understand is the highest between
> Chicago and New Orleans and since this is the bread basket of the U.S
> the ground loam is excellent.

1. Absolute height above sea level means nothing. What is important to TOA is your relative height above the terrain within a mile or two of your tower. I operated from Colorado for ~30 years and always got a chuckle from the guys who said, "My antenna is over 1 mile high". In fact what is important for determining TOA is not height above sea level but height above surrounding terrain.

2. Ground conductivity has minimal effect on horizontally polarized ground reflections. You may be thinking of vertically polarized antennas like verticals where it has a huge effect. HFTA does have conductivity as an input parameter but it has minimal effect, at least in my case (average ground versus salt water).

> I use 7/8 andrews plus a long length
> underground and the tower is hinged in two places
> as well as another one for array tilting.

Phsical tilting has minimal effect on the ground reflections for the angles of interest (4-10 degrees) because the vertical lobe is not very narrow (typically a Yagi has ~50 degree 3 dB vertical beamwidth). In other words tilting has a far secondary effect on TOA versus changing the antenna height. You can prove this to yourself by modeling with a program like EZNEC (HFTA does not allow tilting because it is physically impractical and has little effect).

> Pretty simple question for
> those who know the answer after all you start off with 3 db gain in two
> different directions thereffore it would seem to me that a yagi was
> only 50% efficient

I believe you're referring to a dipole which has 2+ dB gain over isotropic in the two directions broadside to the element. If we add ~6 dB from ground reflection gain, we get >8 dB gain over isotropic, but this is ONLY for a specific TOA which is determined by the antenna's height above ground. Of course a good Yagi will typically have 25-30 dB Front to Rear, so its backward lobe has very little of the total energy (far less than 50%).

Bottom line to all of this is that your antenna's height above ground has the primary influence on TOA. The only other way to "steer" the vertical lobe is to mount your antenna on a motorized tower (unless you go to vertically stacked elements and phasing).

Put your single antenna at 120' and the vertical pattern will be centered on about 9 degrees (assuming flat terrain).

73 & GL!

Bill W4ZV

P.S. Here are some results using HFTA for my 10 meter 3-stack:

Don't have to. Moss won't grow on copper oxide. In fact, we add copper
flashing to the peaks of our roof line to prevent moss growth on the
shingles.

How do you know this? What proof do you have for that statement?

>The other line was coated with wetting agent, which some of us might think
>was an artificial substance to be coating it with.

I'm not going to defend Wes here but do you really feel for a moment
that a couple drops of detergent soap to a gallon or two of water
would really make that much difference? My gwad, what about salt
spray, pollen and dust accumulated on my line?

I noted that it was stated (in an earlier posting on this thread) that
I had used an unauthorized procedure. Pray tell just who do I contact
to get necessary authorization - EPA, OSHA, or?? I just took the
advise of the supplier who recommended for those living is a wet area
(like me) to coat the line with car wax, spray it with pledge or a
silicon spray - I choose the latter. Something wrong taking the advise
of someone experienced with the product?

Are you by chance a government employee?

I do wonder if you have any experience living in an area such as mine
because if you did you would know that here on the northern California
coast we have a lot of rain (over 65" last year). Coupled with that I
live about ï¿½-mile from the ocean and also have a lot of heavy marine
fog. Here the three Ms (moss, mildew and mushrooms) grow very well
indeed.

{An aside: Roy, if you're reading this no comment about the fourth M.}

If you don't want to give any creditability to what happen to me -
fine. Or if you believe through the miracle of applying silicon spray
makes moss grow where otherwise it wouldn't - that's fine too.

Probably the topic most often heard here is digital... Interfacing,
coordinating IPs, hooking the system into the Internet, configuring
operating systems, and getting some one's station to work in the
system.

Lots of discussions on antennas which is pretty much the same as years
gone by.

RACES

On average, I think the technical discussions go deeper now than when
I first got on. OTOH people are people. When driving we comment on
traffic. When hung over we tend to ... well...never mind.<:-)) So
topics other than the technical ones are pretty much the same whether
now or then.

Fully undertstood when referring to planar arrays

Of course a good Yagi will typically have 25-30
> dB Front to Rear, so its backward lobe has very little of the total
> energy (far less than 50%). F/B for planar arrays is for a single angle , front to rear
is more appealing but at the same time it ignores pattern lobes in all directions including
upwards. I have found that TOA on its own is pretty wothless as one can get the gain of a
larger antenna with a wider but narrower lobe that follows the bottom half of a higher gain
lobe. Lets face it for planar arrays gain is obtained at the axpense of half power area.

>
> Bottom line to all of this is that your antenna's height above ground

> go to vertically stacked elements and phasing).

Obviously height is important and totally constrictive of all planar
arrays where the TOA is captive. As soon as you add another vector such
that the array is three dimensional as with a stack things change
>

> Put your single antenna at 120' and the vertical pattern will be
> centered on about 9 degrees (assuming flat terrain).

I assume you mean vertical elevation and yes mine cannot be much over
100 feet
and I will have various lobes available at various TOA's and most
important variable beam depth to accommodate propagation changes as
arrival angles change
Thanks for the contact The most interesting thing that I am looking
forward to is operation at the bottom of the cycle to see if there is
still propagation but only for low angles. As you gat older you look
for any excuse to stay indoors

Hi Mike,

In fact you are trying to rope in three species to do the same thing.
Mold is a fungus as is mildew, moss is not. Mold is often intolerant
of light (rainy regions offer plenty of sun-free days, I only have to
glance out the window to confirm this - but not today.). Fungi are
not even in the plant kingdom.

Moss is not a fungus, it is a plant. Along with Lichens, I've seen
plenty enough growing on rocks to know how little is needed for
nourishment. Contrary to the Fungi's lack of sunlight tolerance,
Mosses survive quite well, and sunlight is more a threat to their
water supply (evaporation). Simply put, Mosses are very different
plants.

Nalgene may be *resistant, but it is not *proof (remember how they
changed advertising of watches decades ago?). Mold has been known to
destroy EVERYTHING, even other molds.

Certainly this demands exceptional circumstances, but that is why it
has been reported here: exceptional circumstances have been found and
not as rare as some might believe - certainly in this region.

You're welcome. Here is a long but interesting story related to low
angle TOAs. W3CRA was a legend and I can vividly remember him working
one Asian after another that I could not detect the slightest trace of
using a 3 element Yagi at 60' from my home in NC at that time:

http://users.vnet.net/btippett/w3cra.htm

Good luck with your new system!

Source record: 52322

Thank you for all your suggestions.

About the energy requirments... we do have one. 200 joules for a 21
meter race (its a small robot) and an allowed "production budget" of
CAN 100 (the robot, if mass produced, cannot cost more then $100 to
build).

I was thinking of having the robot o forward (with no control for
that), and using the beacon to correct my course.

The prefered solution is to build the bugger so well that it just
travells straight for the 21 meters... but alas, another requirmet is
that some sort of guidance system must be included (usually this
project involves obstacles the control system must avoid, the professor
took those out since the race is outside).

Cheers,

G_dir

First, we are talking about two different things here.

Thing one:

Ladder line grows moss - or whatever you had growing on your line.

Thing two:

Ladder line shows some significant loss when wetted.

When you try to combine the two, you can make my points look pretty
silly. But I'm not saying that putting wetting agent makes moss grow on
ladder line. I don't think I ever said that.

On the other hand, PE is a Thermoplastic. And as such, there are things
that can have an effect on it that might allow opportunistic life forms
to grow on it.

Okay Danny. I see I have to wordsmith with ya. Forgive me if I get a
little long winded here. When we have to be exact, it can get that way.

I apologize for using the term "approved". You applied a substance to
the polyethylene (or polythene for our friends across the pond)coating
on the twinlead, that under certain circumstances may have caused a
chemical change in the polyethylene. It is possible that the silicone
spray that you applied may have contained such a substance. I don't
know, because you didn't disclose the brand. One might look up the
brand's MSDS to see what the product contained.

Just read your page... very interestin. We don't have large hills in
Illinois but a helicoptor pilot stated that this town is visible for
miles around and another ham told me that the DX bureu staed that this
town got more cards than all of Chicago I remember once when I gave a
local talk where I spoke about Lawson and his work and I repeated some
of his statements. Well I was challenged on some things but since I am
not a DXer they and the suurounding counties waited until a rare
station was comming on and taking only three stations from each
district. Boy I got a shock with the noise and pandemonium and couldnt
see how any station could be picked out but I was fortunate plus two in
the Chicago area. I know I was very lucky and have no idea why people
collect those things or enter contests... the noise is horrible I think
I had 13 elements on a 60 foot boom at that time plus a couple of
reflectors to experiment with. From that moment on I gave up on
aluminum elements and now use exclusively telescopic fishing poles with
an aluminum shell as it is cheaper in the long run and not susceptable
to ice build up

Richard
why don't you get with it instead of the constant adverserial role
Go to the library and get a good book on antennas and maybe study up on
curls?
Oh shucks I forgot you were bald... Never mind keep talking to yourself
and maybe there will be an echo for you to talk to and belittle.
Frankly to me you are just a bore
that struts around in shakesperian tights and write in the language of
my forefathers
and glory only in your perceived triumps in the repair shop. Why not go
back and try to repair some shoes of some people which you cannot fill
See you finally got a response but don't bank on a lot more until you
become less adverserial with respect to all work other than your own
and provide the same respect that you one time would like to receive
Put me in your plonk file and I will respond also

Art,

Why do people run Marathons, race cars, boats, airplanes or turtles? Some like to walk, some roll in the mud, some like to compete in the stadium.

Contesters like to prove that they can design better antennas, assemble better stations and prove that they are better operators. It is also real test for antenna designs and propagation knowledge and how to exploit both for better results that can quantify the performance and weed out junk and junk science. It takes years of devotion to show up in the top ten listings. If you have revolutionary design, we contesters will be first, dying to use it and cream the competition - that's the real test and not mumbo-jumbo claims.

BTW I have a "secret weapon" too, it is a ferrite stick in the dish. Very efficient, no side lobes, one sharp beam, no side or back lobes. It is right up there with EH, Freaktals and perpetual motion machines.

If you assume that propagation between you and UK is as you describe, you are way off. We are also ducting, use skewed path and changing angles depending on the point in the sunspot cycle, sun' activity, etc. etc. So for optimum propagation one needs either antenna that has wider beamwidth or sharp and stearable one in H and V planes.

Can you enlighten us about your new revolutionary invention? Is it better than your patented reflector that is shorter than the driven element?

> . . .

Classic ladder line and punched PE "window line" differ in several fairly obvious ways, of course. First, the spacing of window line is typically closer, so the leakage path is shorter. Second, the impedance of window line is typically lower than window line, so the effect of shunt Z on the impedance is less when the line is matched. But high SWR could move the advantage either way, and for different load impedances either type could have the higher SWR. Third, the fraction of the line which is actually air-insulated is less with window line. Fourth, the shape of the insulation is different -- flat with window line and typically round for ladder line. This impacts the surface area involved for potential leakage, and the way water might adhere. And finally, the type of insulation is usually different -- PE for window line and various materials for ladder line. (The coating of PE on the wires on the sides of window line "windows" wouldn't make any significant difference, except maybe to have some impact on how water would flow on or off the insulating sections.)

Each of these will have some effect on the loss when wet, and different effects as frequency and SWR change. As for the effect that I mentioned where the loss could change quite dramatically with frequency or load impedance depending on the position of the insulators relative to the standing wave -- that won't happen at all if the insulation is solid, and would be most pronounced when the insulators are distinct and periodically spaced. So window line would fall somewhere in between.

>I was thinking of having the robot o forward (with no control for
>that), and using the beacon to correct my course.

Hi OM,

Still very simple. A single, broad beam of light. A dual sensor that is aimed "bore sight" to the direction of the robot's forward motion. Even with RF at 5 GHz, the ability to discriminate is going to be very poor. When both sensors see the light, equal displacement to the steering (they cancel). When one sensor sees the light, then a correction to steering until both see the light (they add).

If the robot thrashes (zig-zag) down a practice course, then reduce the amount of steering the sensors add. If the robot loses track of the beam, then turn up the amount of steering the sensors add. If the correction makes slow looping curves, put horse blinders on the sensors so they can only see a 10 degree field of view and turn up the gain.

The best solution will always have some error in it (correction circuits have to have something to work against). This means the optimal design given your constraints will have some weave. It will travel 22 to 24 meters to finish that 21 meter course.

4596. 6 meter discone modification

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-25 09:52:01 UTC
From: wz0zzz <poetryman@seedsandweeds.com>
Message-ID: <1159177921.505718.205720@k70g2000cwa.googlegroups.com>
Source record: 52233

I was reading an earlier thread about the Radio Shack Discone antenna and saw a post from Wayne about using a ham stick to replace the top whip. I am wondering, since I have a couple of discone antennas and an extra old CB whip, if I trim the whip down, what would be the best length to cut the whip for optimum 6 meter transmitting on 52.525? There's no point in cutting it for the lower ssb portion of the band, since that's all horizontally polarized traffic. And since I have two discones, I am not worried about any effect it may have on frequencies beyond 6 meters.
I don't have a ham stick, and since I have a nice long whip I no longer use, that seems like the best thing for me to use. I'm just unsure of what effect the rest of the discone will have on the vertical element, if any, and what length to cut the whip.

I was experimenting with the antenna, switching the longer rods on the upper horizontal section of the antenna and the shorter rods for the lower ground plane to see what sort of reception I would get, but couldn't put it outside due to concerns the elements might break. I have had trouble with that in the past and had to order new elements. The antenna is definitely flimsy when it comes to construction, but I haven't had any antenna outperform it for reception over a wide range of freqs. As far as performance, it wasn't much different, though it was slightly better on lower frequencies and not quite as good above 2 meters. And since the antenna would never survive a wind storm set up like that, there's no way I would put it up on the roof in that configuration. It is disappointing that they chose to make it so cheap, but knowing Radio Shack, they probably did it so no one would get the idea of making such changes and eliminate sales of their other antennas.

My name is Lorenzo Crescini and I'm Italian. These "Flashes on
Good and evil" reflect the same mood characterizing the Flashes on
the Holy Gospels and Turin's Holy Shroud I wrote in Africa: making
myself useful to our Lord Jesus Christ.
I will start by quoting the best Prayer to Jesus I've ever read.
At the very beginning some reflections concern the devil one.
I thank all those who will read me, write to me, will ask for an
explanation and those who will be able and willing to advertise what
they read by Web, the press or however they like.
I am confident that the last of my Reflections containing a few lined
short account of my life, will be devoted to all of us who are proud
of the Lord.

Web site
www.lorenzocrescini.it/reflections
personal e-mail for communications
ricercapap@lorenzocrescini.it

Best regards

Here are three Reflections as an example

24) One cannot or mustn't say to those who are ill and suffering: "
That's God who puts you to the test". In this way we would offend
The God of Endless Love who cannot wish our suffering. One needs say to
those who suffer: " God's Son himself suffered because of evil, but
you will also resurrect with Him, as He did". That is the truth and
only the truth can give one who suffers the Hope which won't let him
fall into that despair the devil one wants to seize his soul and
conscience! Saying: "it's God who puts you to the test" gives a
suffering man the same relief a learned lecture on food chemistry gives
a starving one.

29) We can give or take from God, Creator of all things, nothing,
except for two things: we can take from Him Honour by offending Him
with our refusal, we can give Him our love, by accepting Him in our
heart! With what insolence might we wish or boast His Light one day,
we, if we had denied Him all life long, being able to believe Him and
not doing that?

38) There are many Evangelic miracles showing the spontaneity of a
memory, neither built nor adapted, which nevertheless is engraved in
the memory of those who were present to the event. It is from conveyed
small details that the truth of the memory of a lived and handed down
episode transpires.

4605. Please identify this vertical antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-25 17:40:22 UTC
From: davis@space.mit.edu
Message-ID: <slrnehg543.2c6.davis@aluche.mit.edu>
Source record: 52242

Hi,

I created a "omni-directional" vertical antenna that NEC-2 reports to
have a free-space gain > 4 dBi. The shape of the antenna looks like:

```
------+
A |
| B
|
+-----+
C * (* = feed point)
+-----+
|
|
|
------+
```

The lengths can be adjusted to give the antenna a 50 ohm feedpoint
impedence. The overall length of wire forming the antenna (4A+2B+C)
is on the order of 1.5\lambda and the height (2B) is something like
\lambda. I built this antenna for 2-meters and it seems to perform
quite well. The .nec files and parameters are available from my
antenna pages at <http://www.jedsoft.org/fun/antennas/omni.html>.

I am sure that I am not the first to create this simple antenna,
nevertheless a google search has turned up nothing similar. Have you
seen such an antenna before and if so, what is it called? I suspect
that it belongs to some class of antennas (antennae?). I would
like to give the proper credit and name for it on my web page.

Also, if you can find a flaw in my NEC modeling of the antenna, please
tell me. The prototype that I built does have an SWR of 1.05:1 as
given by my uncalibrated meter at the design frequency.

Thanks,
--John

Hi John,

A Stub Fed Doublet. A Stub Fed Dipole. A Stub Fed Short Dipole. A
Stub Fed Short Dipole with End Loading. Take your pick.

The end loads can be removed and the stub lengthened to 18.5 inches to
re-obtain resonance at a higher Z to demonstrate two principles:
1. End loading increases current into the structure to lower its
resistance;
2. Stub tuning works.

Several comments. What's with the curious cogging of the SWR computed
from NEC2? EZNEC predicts a quite smooth curve. Your measured values
suggest nearby losses. What do you do to snub common mode currents of
the nearby transmission line that is precariously close, and co-linear
with the polarization of your vertical dipole?

Hi John

I really got interested in the configuration you show for the antenna.
But, when I looked more closely to the Elevation Plane Pattern that looks so
narrow (high gain), I realized that the antenna is very much the same

pattern as a basic full wave center fed wire.
The graduations on the plot graph was misleading to me.
Perhaps there is something special about this antenna that I am missing.

Jerry

I think I prefer "Stub Fed Doublet".

>Several comments. What's with the curious cogging of the SWR computed
>from NEC2? EZNEC predicts a quite smooth curve. Your measured values

I was also wondering about that. The SWR values are computed by
xnecview. It is conceivable that the choppiness of the curve is due
to numerical stability issues, e.g., using the difference of 2 small
numbers. Tonight I will dig out the xnecview source code and
investigate further.

>suggest nearby losses. What do you do to snub common mode currents of
>the nearby transmission line that is precariously close, and co-linear
>with the polarization of your vertical dipole?

For the prototype, I tried to run the coax perpendicular to the
polarization to minimize the issue. Eventually I will use something
like a 1-1 choke balun. In fact, at the bottom of the web page I
suggest that something like that should be used. Of course I am
open to other suggestions.

Thanks,
--John

4614. Elevation Patterns of Ground Mounted Vertical Monopoles

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-25 20:00:13 UTC
From: Rich <rfry@adams.net>
Message-ID: <1159214413.797517.323390@m73g2000cwd.googlegroups.com>
Source record: 52251

Earlier in another thread I posted the text below, and thought it would be useful to show some documentation for it, and also give it more visibility.

QUOTE The point I'm pressing is that ground-mounted verticals up to 5/8-wave high used by ham operators have the same elevation pattern shapes as those used by broadcast stations. The peak radiation launched from all of them occurs in the horizontal plane, and reduces slowly and smoothly for low elevation angles above the horizontal plane. It could well be that the DX you do work results from radiation at a much lower elevation angle than believed possible when looking at the usual NEC calculations and plots for that vertical antenna. END

The link below leads to a scan of a graphic from Section 10 of Terman's Radio Engineers' Handbook (1943). It shows the "takeoff angles" needed to serve various distances from a ground-mounted, vertical monopole radiator via skywave, and the resulting skywave fields there for the conditions stated. The reflection coefficients apply to the E-layer.

Terman's work shows that the elevation pattern of such a radiator over lossy earth does not approach zero field near the horizontal plane -- as is a common interpretation when looking at their NEC evaluations.

Terman's text (p. 743) also states that the reduction in skywave field after a peak at ~160 miles results from the ERP at elevation angles serving those ranges not compensating for the greater losses of those longer paths.

But the skywave fields at 1000+ miles and takeoff angles of 1 degree and less are far from approaching zero (no matter what we think NEC is telling us).

I believe that this antenna can probably be placed in the general
class of center-fed collinears. Other antennas in this class include
the center-fed fullwave, the classic Franklin antenna, and the EDZ
(extended double Zepp). The "Super-J" is a somewhat-similar design,

but is end-fed rather than center-fed.

The center-fed collinears of this sort tend to have a high (and/or rather reactive) feedpoint impedance. They're usually fed through a section of transmission line - often shorted at the end and fed via a tap partway up the section... the "universal stub".

Based on the dimensions you posted, it looks to me as if this antenna is pretty close to being an EDZ, but with the ends of the radiators bent back sideways. I'd guess that by bending the ends sideways, and fiddling with their lengths (and that of the matching section) you've been able to match the 50-ohm feedline impedance without needing a shorted/tapped matching section.

The elevation pattern of the antenna shows a hint of the high-angle secondary lobes which characterize an EDZ.

So, I'd conclude that you've developed a variant on the EDZ (or something partway between an EDZ and a center-fed fullwave) which yields slightly lower gain than an EDZ but has a simpler matching section.

The one thing I'd watch out for, with this design, is the folded-back ends of the radiating arms. This design puts these high-voltage, high-impedance points right at the mast, and this might make this antenna more subject to mast/antenna coupling and de-tuning than a traditional EDZ or full-wave center-fed.

The old ARRL VHF handbook has quite a bit of information on these sorts of collinears, and has a nice writeup on the "universal stub" matching technique (not very well known these days, but quite useful).

Sorry you feel that way. These will Help:

Step 1: No more automatic renewals. Individuals must retest and
pass all elements required for their license class.

Step 2: The passing score for written exams needs to be raised to 85%.

Step 3: Code elements should be 13 wpm for General, and 20 wpm for Extra.

Step 4: Make the no-code license one year non-renewable.

The resulting antenna is nothing more than a 1/4 wave groundplane on 6M- and
has none of the wideband characteristics of a discone at 6M.

My HAndheld trips my GFCI breaker. I have inguired on some of the groups specializing in electrcal information without help.
I was hoping there would be those here who have the backgrounfd in both electrical and radio that can help.I have connected some .005uF capacitors from the load side of the GFCI breaker to ground and instlled a clamp-on ferrite bead aroung the neutral and hot wires. This fixed the problem but I was told I shouldnt do this as it might effect the operation of the breaker.

Presumably because the imbalance current caused by the unbalanced
active to earth connection will contribute to tripping. Work out the
current in the 0.005uF capacitor on the load side of the breaker,
remember its phase relationship to resistive leakage currents, other
bypass capacitors in line filters, and compare it to the nominal
unbalance trip current to see if you should be unduly worried.

Some years ago, there was an article in QST about using trees as antenna. There was a sort of toroidal winding in the air, the tree beeing in the center. If I remember well, the article reported experiences in the army.

Do you remember ? Can you give me more information ?

Thanks a lot !

Hi OM,

There was some discussion of this in this group about 8 - 10 years
ago. Most thought it was absurd. Some thought it was possible. None
considered it very effective. One reported experience (and he was
thoroughly mocked). The tree was treated as a vertical radiator, and
was fed against ground and into a nail to penetrate to the conductive
fiber. Some form of matching was generally necessary.

The absence of discussion in the intervening years would suggest this
idea is not one to be taken very seriously.

The Livewire Yahoo Group had some discussion of this a year or two back. I think it was a kind of spinoff of their experiments with Ionic Liquid Antennas. If you are interested enough they probably have all that in their archives.

Just lay them out on the bottom like you would on the ground... The
fish will not even notice the wires... Fresh water is not a good
conductor so there is no advantage to putting them in the water.. And
there is no great disadvantage either... Should work just fine...

The Military certainly did experiment and use such systems, particularly during the Vietnam war.

There are several papers floating about on the subject, such as those from the United States Army Electronics Command (ECOM):

"The Effects of Foliation on Transmission from a Toroid-coupled Tree", ECOM Report No. 3473, September 1971
"Signal Propagation at 400 kHz using an Oak Tree with a HEMAC as an Antenna", ECOM Report No. 3504, November 1971

"Performance of Trees as Radio Antennas in Tropical Jungle Forests", ECOM Report No. 3534, February 1972

"Utilization as RF-Antennas of Live and of Lifeless Structures in Natural and in ManMade Jungles", ECOM Report No. 4133, June 1973

When Terman did his work what were considered to be "the broadcast frequencies"? Even on 80 meters we are well above that range from that era... There is a major change in polarization response as we go from 160 to 80 meters, and again to 40 meters, etc.

As an active antenna experimenter on 80 meters who keeps records of which antenna made which contacts, and with the ability to switch between relatively high horizontal antennas, and vertical antennas of both a quarter wave and a half wave in height (80 meters), I can tell you with certainty that less than 5% of my 80 meter DX contest contacts in 04 and 05 were made on the vertical antennas ... It is the rare DX station that is clearly better on the verticals compared to the high dipoles - and when they are stronger on the low angle verticals it is usually right as the band opens or closes... Based upon my antenna testing in previous years, for this year's CQWW I am replacing all the vertical arrays with horizontal arrays... At that point the only vertical arrays I will have left is on 160...

My gut feeling, based on real results over multiple years, is that the incoming HF signals rarely peak below 10 degrees - probably less than 5% of the time...

Another issue in Termans work is his decision to characterize the the F layer as a reflecting mirror... We now know that the ionosphere refracts and ducts signals as often as it reflects them... I can suggest that too low of a launch angle of the main wave is deleterious for HF DX in that such a shallow angle of incidence against the lower boundary of the F layer allows only reflection and does not allow the wave front to enter the ducting region higher up, which limits you to less than 1000 miles first hop.. Whereas a steeper launch angle results in the wave front penetrating the bottom of the F layer, being refracted to a shallower angle once inside the ducting region, being ducted long distances with far less absorption than it would for multiple hops, and then again refracting and exiting the duct at a steeper angle than one would expect for such a distance... This to my mind is a common mechanism for those amazingly strong DX openings we see...

Simply put the clamp-on on the third wire neutral at the GFCI.

It does not have any impact on GFCI operation or safety issues.

If I remember correctly, in the fog banks of memory, bypassing inside the wall service box is frowned upon by insurers and possibly violates the NEC [USA].

I'm getting old, memory stalls at times, but I remember something from the late 1950s [college days] regarding bypassing inside the wall box is NAW NAW NAW.

Sorry, that's a misunderstanding. He states using the E layer in his Fig 55 and in his text.

>... I can suggest that too low of a launch angle of the main wave
> is deleterious for HF DX in that such a shallow angle of incidence
> against the lower boundary of the F layer allows only reflection and
> does not allow the wave front to enter the ducting region higher up,
> which limits you to less than 1000 miles first hop.

On page 749 of this chapter, Terman writes, "If it assumed that 3-1/2 degrees is the minimum practical angle above the horizon at which rays can depart from the transmitting antenna, the maximum skip distance theoretically possible is about 1,700 km for E-layer transmission and 3,000 to 3,500 km for F2-layer transmission. When communication is to be carried on over longer distances the transmission path must include two or more hops..."

But if the vertical monopole has an unobstructed path for rays between the optical horizon and +3-1/2 degrees elevation, then those ranges for a single hop would increase.

And the reason that 3-1/2 degrees might be a practical limit is not related to the belief that a ground-mounted vertical monopole has no radiation in that sector. In fact its relative field in that sector for all practical purposes is the same as it is in the horizontal plane, where it equals 100%.

The link below leads to another of Terman's graphs, this time showing the measured fields vs distance out to about 2600 miles with MW freqs between 640 kHz and 1190 kHz . About these curves Terman writes," At great distances from the transmitter the skywave intensity drops off more rapidly than inversely with distance (see Fig 56) presumably because the reflection coefficient becomes less when the angle of incidence of the skywave approaches glancing, and also because at at considerable distances the skywave may have made two or three round trips between the ionosphere and the earth before reaching the receiving point."

It might be worth while trying a different brand of GFCI. I've read
that some newer models have better resistance to false triggering from
RF.

I think trying a different brand of GFCI is a good idea. In my experience, in my house, I have had some that fail and just trip, no matter what's plugged into it. Buying a new one solved the problem. I have also noticed that the number of years they last varies from one GFCI outlet to the next.

In all cases, when the outlet needed to be replaced, it would continually trip to the point it didn't do any good to have anything plugged into it because it wouldn't get power. That is really good though, because you want the device to fail that way rather than to fail, still supply power, and you not know about it.

Hi Zack,

You may be confusing (or have been confused with the content of this thread) antenna effeciency with system efficiency. The page makes the point of there being a feed "appropriateness." I would suspect the method of feed makes the difference (and those issues that lie beyond that include method of detection, noise, and so on).

As for putting it to the antenna's merit, the roughness is far more significant to shorter wavelengths (roughness is on order of eight wave). This in itself produces problems of phase control, and phase control is the name of the game in directivity.

Yup, I made a typo when I said "F" layer in relation to Terman's discussion of the E layer, - probably because I intended to discuss the F layer...

But, I bring us back to the topic, no where do I see HF mentioned in the quotes from Terman... Ground wave transmission becomes markedly poorer beginning somewhere around a thousand KC - which is why hams were relegated to the waste land of 200 meters and down....

BTW, here is an interesting discussion of the D and E layers for VLF propgation...
http://www.aavso.org/observing/programs/solar/vlfprop.shtml

But to bring us back to the major complaint which seems to be that the Nec engine doesn't model the last few degrees over ground very well, so that the zero angle is discarded by the software... Richard seems on a mission to prove the NEC engine wrong - well, I agree, the NEC engine does have limitations for low angle signals which is why the authors have installed an angle cut off... Per Richard's citations, Terman's data proves that for MW signals - but not for HF (a different kettle of fish)...

If we look at the ham antenna literature over the 50 years predating the advent of the NEC engine, we do not see much championing of the 5/8 wave vertical for lower HF... Since these folks did not have the NEC engine poisoning their thinking one has to ask why the lack of interest... The explanation for that, in my mind, is because it does not have significant propagation advantage at HF offsetting it's greater mechanical and financial burden to install... And because the high angle lobes that are beginning to bulge are disadvantageous with an antenna that is intended for low angle receiving/transmitting...

In my case I have a 4/8 wave vertical for 80 meter sitting on an elevated base... Extending it to 5/8 wave would be a trivial task - but I see no advantage to doing so...

Hi Denny,

Having done a bajillion designs in EZNEC, I take exception to this comment for two reasons:

1. The low angle signals portrayed (or modeled) are easily demonstrable and are certainly experienced by the any Ham;

2. EZNEC (notwithstanding other packages) easily offers 0 degree field data that is within 1 dB of the classic Brown, Lewis, Epstein findings.

If there is any anachronism in the NEC packages; then it is the presumption of an Earth with infinite radius (no curvature). Here, the far field curves diverge from the near field projections (and yet you can still recover from that divergence if you wish, it is merely tedious).

Another note! When it comes to 160 meter vertical antenna's you can get
a lower take off angle (TOA) from a full 1/4 wave vertical or
electrical 1/4 wave tee vertical of 10-20 deg., versus ~30 deg. with
the inverted L. However it's a moot point as the night time E layer MUF
blocks 160 meter low angle transmitted radio signals from ever reaching
the F layer to be propagated. So unlike with HF propagation, MF
propagation success does not require the lowest of take off angles.
Also higher take off angles of 30-40 deg. via the inverted L are better
able to take advantage of the low signal loss E valley-F layer
propagation duct mechanism, a form of Chordal hop propagation.
****
****
>unquote

OK, so we are mixing theory with empirical results here, but, if having
the lowest possible angle of antenna response at 160 and 80 meters was
the best, by now a majority of the flagship contest stations would be
equipped with 5/8 wave vertical arrays, and they are not... I only know
of one major contest station that uses a 5/8 wave vertical on either of
the bottom HF bands...
My own experience is that the 1/4 wave vertical is superior on 160 but
not on 80... Nor is the half wave vertical on 80 superior to a high
dipole... The 80/160 vertical sits over a hundred half wave radials...
The high dipole hangs over forest with below average sandy soil......

Just to point out that, although groundwave _propagation loss_ is greater when progressing from lower to higher radio frequencies, the radiation patterns and peak gains in the horizontal plane from ground-mounted vertical radiators remain the same for corresponding radiator heights in wavelengths and equal r-f ground resistances, no matter what the frequency.

All ground-mounted, vertical monopoles through 5/8-wavelength in height develop maximum radiated relative field in the horizontal plane. If the vertical radiator is 1/4-wave tall, then the _radiated_ elevation pattern is approximately a function of the cosine of the elevation angle, no matter what the ground conditions are, at and near the radiator site.

These are the distinctions I am trying to make, because the common belief seems to be that the relative field of the elevation pattern launched by a ground-mounted vertical is dependent on ground conditions, and always zero in the horizontal plane to peak at some greater elevation angle.

The field strengths measured by Brown, Lewis & Epstein in the benchmark 1937 study defining an effective r-f ground were taken at 3 MHz. And for the best-case radial ground system the groundwave fields at 3/10 of a mile were within a few percent of the theoretical maximum possible for that radiated power over a perfectly conducting earth -- even though the tests were done in NJ over a path of rather poor conductivity -- maybe 4 mS/m. It's clear from this that even in the low HF spectrum, the field radiated from their test antenna over a poor earth path was not zero in the horizontal plane!

(infinite size, perfect conductor, perfectly flat).

NEC models would suggest that the major lobe of a monopole up to 5/8
wave over "real" ground is dependent on the ground characteristics,
and can be quite high relative to the 0deg to 3deg region that people
are focussing upon.

For the shape of the relative field elevation pattern, it is true in general. A poor r-f ground for the monopole (i.e., a ground of high r-f resistance) will change the peak gain of that radiated elevation pattern, but not its shape.

NEC evaluations typically don't show 100% relative field in the horizontal plane in the elevation pattern radiated by a vertical monopole except over a perfectly conducting ground plane, which is the root of all this confusion.

Once the radiation is launched, then it becomes subject to the propagation losses for the path and frequency. But for verticals up to 5/8-wave tall, peak relative field always lies in the horizontal plane, regardless of the ground conditions on and near the radiator site. This is the basis used by the FCC in determining the coverage capabilities of AM broadcast stations, and has been proven to be a rather accurate approach going back some 60 years.

I'm relatively new to the group, but I can already tell you're the group troll.

Having been active in the rec.photo groups for sometime, I understand trolls, but at least you have a beef with something tangible.

Let's face it. You most likely are one of those who got their General at 13 WPM, maybe their Extra at 20 and hate the no coders and those who got their license by only taking code at 5WPM. Well, who cares. It's time for you to accept reality and come to the conclusion, you out lived Morse Code. Get on with life.

Jim Philopena
KB1NXE - Formerly KA1VGP, DA2PJ and WN1VJW

If you have a Call Book with that last one in it, you have definitely out live Morse Code - time to get back to ashes and dust.

No, not at all. There is a lot less cussing, spitting, passing of gas into the mike, usually no electronic sound effects, and rarely a "10-4 good buddy." I'd say the average ham has an 80 point higher IQ, than the average Cber.

Don

>Several comments. What's with the curious cogging of the SWR computed
>from NEC2? EZNEC predicts a quite smooth curve. Your measured values

I looked into this. The feedpoint impedence values Z(f) that NEC2
reports have discontinuities or discrete jumps, causing the predicted
SWR to have the same. I imagine that this is a result of the
numerical approximations and the segmentation used. Does EZNEC report
the oscillations when the frequency increment is on the order of 0.01
MHz? What version of NEC does EZNEC use?

I also tried using the extended thin wire kernel, but it did not help.
Nor did increasing the segmentation.

Thanks,
--John

>yields slightly lower gain than an EDZ but has a simpler matching
>section.

What sort of gain is expected from an EDZ? I tweaked the topology
of my design a bit in the hope of getting a broader bandwidth, but
instead got even more gain. For example, the version represented
below has a minimum gain of more than 4.7 dBi (at the side) and more
than 5.25 dBi in the forward direction. Previously I reported gain
values that ran from 4.2-4.7 dBi. So this one represents a bit of an
improvement. I may try building it this weekend. Thanks, --John

4675. First homebrew antenna and a question

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-27 03:57:56 UTC
From: jawod <jawod@fuse.net>
Message-ID: <c4ffb$4519f730$4831cd39$547@FUSE.NET>
Source record: 52112

I spent the day lowering the folded dipole that I BOUGHT. I was unable until recently to find how bad the SWR was on most bands. The only reasonable SWR was on 17 meters.

So, I replaced it with a homemade G5RV, measured appropiately for each leg of the dipole (14AWG) and for the 300 ohm window line to R/G8U.

I now find reasonable SWR on most bands (WARC, not so much). Here's the deal: min SWR comes in right at 3.5 MHz, 6.75, 13.43, 18.07 and 29.06. It appears that I made the classic newbie mistake...antenna too short.

Now, since I am using an ATU, I think this should be close enough for acceptable efficiency (at least for 80, 40, 20, 17 and 10 meters).

What do you think?

John
AB8O

PS, When I get the time, I'll try EZNEC but for now, I just want to work what I hear for a change (!)

Dale,
Thanks for the response.
My god, you're right. I think I better get some sleep!

Thanks,

John
AB8O

PS, question still holds...I think I can leave it as is using an ATU, No?

>values that ran from 4.2-4.7 dBi. So this one represents a bit of an
>improvement.

For an EDZ in isolation (no mast) I believe it's around 3 dBd or 5
dBi, plus or minus a hair.

I modelled a copper-pipe EDZ, mounted at the top end of a conductive
mast. This one came out with 5.85 dBi in the favored direction, and a
2.5 dB front-to-back ratio.

```
CEDouble extended zepp for 2 meters
GW 1 7 0 0 2 0 0 6.5 1.25 # Upper segment of mast
GW 2 7 0 0 2 0 0 -2 1.25 # Middle segment of mast
GW 3 100 0 0 -2 0 0 -112.5 1.25 # Lower segment of mast
GW 4 15 0 0 2 13 0 2 0.5 # Upper support bar
GW 5 15 0 0 -2 13 0 -2 0.5 # Lower support bar
GW 6 7 13 0 2 13 0 -2 0.5 # Shorting bar
GW 7 7 13 0 2 17 0 2 0.5 # To top of balun
GW 8 7 13 0 -2 17 0 -2 0.5 # To bottom of balun
GW 9 15 17 0 2 28 0 2 0.5 # To top arm
GW 10 15 17 0 -2 28 0 -2 0.5 # To bottom arm
GW 11 40 28 0 2 28 0 46 0.5 # Upper arm
GW 12 40 28 0 -46 28 0 -2 0.5 # Lower arm
GW 13 5 17 0 2 17 0 -2 0.5 # Feedline attachment
GS 0 0 0.0254
GE 0
EX 0 13 3 0 1.0
```

```
FR 0 1 0 0 145.27 0.00E+00 0.00E+00 0.00E+00 0.00E+00
0.00E+00
RP 0 61 72 1101 0.0 0.0 3 5
XQ
EN
```

A stacked pair of them on a single mast yields 8.85 dBi in the favored direction, with 2.38 dB front-to-back ratio.

Have a look at Fig 4 at http://www.vk1od.net/G5RV/index.htm . Though
the graph doesn't show VSWR on the RG213, the loss is lowest where the
VSWR is lowest. You should be using an ATU, and it is the line loss
that is more important than the VSWR of itself.

Your antenna sytem appears a little long rather than short, did you
measure the length of the radiator conductors, did you measure the 300
ohm line, did you allow for the velocity factor of the 300 ohm line?

Hi John,

I've been using various flavors of E(L/Z)NEC for more than a decade
and I've never seen such dramatic cogging of the data that was not
attributable to construction (notably fractals). Your data is
stranger yet in having correlated noise on the left, and uncorrelated
noise on the right.

When I run the model at the resolution you suggest (0.01MHz), yes, I
do see some very fine cogging. It is on the order of 0.5 Ohm reactive
up tick which, for example, translates to a shift from 1.60:1 to
1.62:1 on a generally downward slope. When I run again with the
double precision math, this goes away. Both curves do not exhibit a
flat bottom, but rather an asymptote.

You can observe this quite readily on the download, free version of
EZNEC for yourself.

Please look at the <ftp://space.mit.edu/pub/davis/misc/nec/swr.png>
for a plot of the SWR using a spacing of 0.01 MHz. I suspect that the
noise that is showing up may be due to truncation error. I believe
that spacings of higher values, e.g., 0.2 MHz result in a different
sampling of the noise.

The version I am using (see
<http://packages.debian.org/stable/hamradio/nec>) contains this warning:

This version contains code which hasn't been extensively tested for
errors, which was input by hand from a report -- use with care. The
numerics are currently only SINGLE PRECISION.

If EZNEC were available for linux, I would look into it. Also, can it
be driven in "batch" mode without a GUI?

Thanks,

Hi John,

Yes, this confirms the shift to double precision in EZNEC lowering
artifacts in the fine data.

However, I think it goes beyond simple matters of single or dual
precision math. When I was designing Fourier Analysis packages while
I was on contract to HP, I discovered there was a world of variability
in math library's transcendental functions.

Microsoft's product was abysmal, whereas Borland's was superlative. A
telling example is that for the transform of a sine wave into the
frequency domain under Microsoft math libraries, the noise floor was
at 60 to 80 dB below the fundamental peak with harmonics. When I
switched to Borland math libraries, there was a single bin response
and the noise floor plunged to 200dB down!

For others following this description, they may wonder at the
terminology of noise floor for a simple sine wave transform. Fourier
Analysis is done by parts through FFTs and this departs from classical
Fourier which is continuous. Because FFTs are discrete (bound by an
arbitrary start and stop), this injects spurious responses into the
transform. On top of that, rounding errors attributable to series
expansions of the transcendentals would give lower accuracy -
statistical (largely uncorrelated) noise. The sine wave transform was
a method of self-validation of the library used and Microsoft failed
big time (especially considering the 10:1 cost differential for the
more expensive M$).

There have been various reports of success and failure when Windows
emulators have been used. I cannot report any personal experience
because my Linux machine is largely confined to Server development
(XAMMP/Wiki/MySQL/RubyOnRails).

The last reports I've gotten are that Wine, the Linux Windows emulator, isn't able to open the EZNEC manual, and has at least one other problem with EZNEC. I've gotten several reports that the SoftWindows emulator for the Mac runs even the professional versions of EZNEC flawlessly. There isn't, and won't be in the foreseeable future, a native Linux or Mac version of EZNEC; the market is simply too small.

EZNEC can be run in something resembling batch mode with MultiNec (http://www.ac6la.com/).

The NEC-2 calculating engine in the demo and standard EZNEC program types contains a mixture of single and double precision variables which does considerably better than a fully single precision implementation but with only a slightly greater memory requirement. EZNEC+ and the professional programs also include a fully double-precision implementation. None of these are identical to NEC-2 (of which there are several slightly different versions in circulation); EZNEC has consolidated scattered constant values, added protections against numeric overflow, incorporates third-party math libraries for some calculations, and has a few obscure bugs in the code fixed, among other differences. Although EZNEC doesn't implement all the features of NEC-2 (patches, for example), it has features which NEC-2 doesn't, such as a comprehensive geometry check and provision for wire insulation (and of course the GUI). I've also found some optimizations done by various compilers which cause errors or crashes in some cases, and of course these are avoided when compiling EZNEC's calculating engines. In fact, I'm just now working with a compiler manufacturer in tracking down what looks like a bug I found in a new compiler I'm considering using for future versions. NEC-2 is free, and people pay for EZNEC. They do get something for it.

Most of those lowest SWR points actually indicate the elements are too
LONG. Remember, the wavelength is longer as frequency is lower.

Thanks to all for replies.

Yep, too LONG.
Egg on MY face. In my defense, it was late and I was working all day
getting the G5RV up in the trees.

To top off the day, I connected my K2 to the ATU and can't get them to
work together...short somewhere...will have to wait until after work.

A 5/8-wave vertical is more expensive than a 1/4-wave vertical for sure. But the high-angle lobe that develops when the radiator height exceeds 1/2-wavelength maybe isn't as serious as thought. At HF, probably the groundwave is gone before that high-angle radiation returns to the earth via skip, so it won't cause self-interference even if you are trying to use the groundwave.

Below is a link to a clip from the FCC website, showing the elevation patterns for vertical radiators of several heights in wavelengths. For a given applied tx power, the sidelobe of the 5/8-wave vertical is significantly greater in radiated field than that of a 1/4-wave from about 60 to 80 degrees. But the 5/8-wave has higher radiated field than the 1/4-wave at elevation angles below ~18 degrees -- which would benefit HF DX.

AM broadcast stations operating full time with 50 kW transmitters tend to use radiators of about 195 degrees in height. This gives them much of the gain advantage over a 1/4-wave in and near the horizontal plane, which helps their groundwave and DX coverage. But radiators of that height have an insignificant high-angle lobe to worsen their self-interference at the edge of their groundwave coverage area. Of course because of the frequency, their groundwave can cover an area having a large radius.

The dipole should be 102 feet for bare wire. Maybe 99
feet for insulated wire. That's 1.5WL on 20m. The
series section should be 1/2WL on 20m. With a VF = 0.9,
that's a little over 31 feet.

According to EZNEC, here are the optimum lengths for
the series section:

3.8 MHz 30.5', 7.2 MHz 34.5', 10.125 MHz 20.7',
14.2 MHz 33', 18.14 MHz 12.5' or 37',
21.3 MHz 29.5', 24.95 MHz 30.5', 28.4 MHz 23.4'

It's easy to see why 31' doesn't work well on
30m, 17m, and 10m.

According to my interpretation of material written by Dick Knadle,
K2RIW published in the ARRL Antenna Book, a reflector error on the
order of 1 inch peak to peak results in a gain deterioration of 0.3 dB
on 1420MHz. I doubt the mesh adds more than another 0.2 dB of loss.
There is still another 1.5 dB of loss to account for the lower
efficiency. Could the dish be optimized for receiving, sacrificing
some gain for a better gain to temperature ratio?

Please be a bit more careful where you plan your responses Zack, I wasn't
the one that posed that question above.

I suppose that they could be under-illuminating the dish in order to
suppress the "hot" ground behind it. For a dish that size though, one inch
is awfully tight. Why don't you ask them?

Art Unwin wrote:
"When one looks at a radiating array pattern one can see that the yagi is very inefficient."

Efficiency is output over input. Antennas can be made very efficient. When radiation resistance is large in comparison with waste (ohmic loss resistance), efficiency is high. Directivity is something else.

Often, Terman answers antenna questions simply. This is such an occasion. Terman writes on page 907 of his 1955 edition of "Electronic and Radio Engineering":
"The Yagi antenna of Fig. 23-39, and the corner reflector, represent about the best that can be achieved with respect to edirective gain in a compact array."

Pity the fool who argues with Terman or Kraus.

Best regards, Richard Harrison, KB5WZI

I'm not against having good hams, but can you tell me what your Inane
proposals have to do with that. Over 30 years I've seen tons of 20WPM Jerks
on the bands. CW has nothing to do with the people we get in.

Have I missed something here? As I understand the EDZ (is it not the Extended Double Zepp?) it comprises a center-fed doublet with a 5/8 wl wire on each side of the feed point. It's broadside gain is about 3.1 dBd, with a narrower lobe than that of a dipole, from which the gain over a dipole is obtained. Am I correct so far?

If so, then we have only a single radiator. How then can there be a front-to-back ratio?

Have you considered using the much simpler moxon? This one has a
forward gain of 5.6-6.4dBi (6.2@146MHz) and a front-to-back ratio of
18-31dBi (29@146MHz). It uses #12 AWG wire. Thanks, --John

Your definition of efficencency was accepted and then a very good answer within the boundaries of your definition was given which you rejected. The fact is if you could recover all the energy that goes into the sidelobes or radiates from the rear of the antenna and place it in the main beam you would increase power in that direction precious little. Apparently what you are seeking is a LASER beam performing in the HF spectrum. Even this would not be very "efficent" for communicating from one point on the surface of the earth to another point below the horizon that is to say you cant send a signal through the Earth. Communication through the air via radio is inherently inefficent if you look at it from the standpoint of thousands to millions of watts at the transmitter with only microwatts being received. In the futre we may learn to transmit nearly all of the power to a distant point. If this happenes the most efficent method of getting an HF signal across the ocean will be a moot point. By then will will be doing matter/energy/matter conversion so that we will be able to transmit ourselves over long distances if this is at all possible. In the mean time hams will continue to make do with a very inefficent medium even by todays standards

It is true that in the past we have accepted many thing that were true which was not, many of these errors have been corrected at what seems to be an expotential rate over the past couple of hundred years. Much of this was accomplished by people viewing the world with a degree of open-mindedness that had never existed in the past and this is a very good thing. Being totally opened minded has it fallicies in making us not being able to recognize when we have the correct answer. My mother as I am sure a lot of other mothers have said this best. "I am open minded, just not so much as to let my brains fall out." It is our closed mindedness that keeps of from running off accepting every BS explantion that comes along

It has been your choice to deem anything someone says to you that you do not agree with as RUDENESS. Perhaps we should all be POLITE to you and let you go ahead with your fools errand. I doubt if most of us could be that cruel. Actually most people are very polite to you in the truest snese of the word carefully trying to explain things to you that you clearly do not understand, trying to explain to you a reality you refuse to accept.

4702. interference question

Newsgroup: rec.radio.amateur.antenna

Source record: 52189

Hello, I have a question about dBi antenna gains. From what I gather, dBi is a unit that specifies the directivity of an antenna and the focus of the transmission power between a transmitter T and receiver R1. A 25 dBi antenna gain then, for example, is referenced to a perfect isotropic antenna.

For an isotropic antenna, received interference power at a receiver, say R2, is simply the transmit power of T, P_T, multipled by the path loss in watts between T and R2 that is computed in dB as follows:

0 dBi + 0 dBi - 32.45 - 20*log10(frequency) - 20*log10(distance)

My question is, how do I compute the received interference power at R2 for the same scenario where T, R1 and R2 all use 25 dBi antennas? I know the positions and path losses between T, R1 and R2, and the antenna gains of 25 dBi. Do I take a percentage of the transmit power P_T because these antennas use directivity? How does this work?

Thanks,
Omar

Yup.

>If so, then we have only a single radiator. How then can there be a
>front-to-back ratio?

The model I developed/posted was for an EDZ, which is side-mounted at
the top of a conductive mast. One half of the doublet sticks up above
the mast "in the clear", but the other half runs down parallel to the
mast, perhaps a foot away.

As with any side- or tower-mounted antenna, there's some amount of
reflection from the mast, and this is enough to create a few dB of
"front to back" ratio.

If the antenna were modelled (or used) in isolation, with no mast and
with the feedline running out sideways, the "front to back" ratio
would be unity or very close to it. Just delete the mast pipe from
the model I posted and re-run NEC.

The design/installation data for Telewave's side-mounted folded-dipole
arrays show several different patterns, ranging from something very
close to a cardioid, to an "off-center circular" pattern, to a nearly
perfect circular pattern. All of these patterns can be achieved using
the same antenna array, by simply altering the length of the
side-mount arms which support the dipoles beside the mast or tower.

>18-31dBi (29@146MHz). It uses #12 AWG wire. Thanks, --John

If I were actually seeking a high front-to-back ratio, a Moxon would
be a good choice!

I actually developed the EDZ models for a different application... the
main antenna on a 2-meter repeater installation. We want a reasonable
amount of gain, and a near-omnidirectional pattern. The high
front-to-back ratio of a Moxon would not be appropriate in this case...
the 2.5 dB ratio of the side-mounted EDZ is probably as much as we'd
want to accept, given the shape and size of our service area.

you have some big misconceptions that i can't begin to address here.. but just a couple of points for you to go study on.
1. the arrival angle is not a fixed value for a point to point circuit. the angle changes with the height of the ionosphere and also with which layers are supporting the path at the time. the angle can change minute by minute, or it can be fairly constant for hours depending on the state of the ionosphere. but it will not be constant for all time.

2. also, it is not like the pretty single ray that some people draw when showing reflections off the ionosphere. the ionosphere is not a mirror, it is a gradient in a layer of ionization. the signals that are 'reflected' are actually refracted and do not arrive perfectly focused as they went up. in addition the polarization is changed which affects the efficiency of the path, this is very evident on 160m and 80m where the prefered polarization can change hour by hour over night.

3. i have no idea where you are going with this idea of stacking is to combat the earths magnetic field. the only effect the earths magnetic field has is on the ionosphere, not on how your antenna works. it is well known that changing the height of a yagi changes the vertical radiation pattern and hence the arrival angles that it favors. stacking yagis at different heights and selecting them separately or in combinations lets you adjust the elevaion pattern to compensate for the changes in the arrival angle. in most cases all the yagis in a stack are fed in phase so their signals combine at the horizon, but there have been some experiments where the phasing is changed to intentionally raise the pattern higher to cover different arrival angles more efficiently.

The gain figure is not a single number (though a single number is
often quoted for the maximum gain), gain for a directional antenna
varies with direction (in three dimensions) and you must apply the
gain that is appropriate to the path (in three dimensions and
considering the effects of ground reflection) at each of receiver and
transmitter.

Your formula looks like the Friis formula for free space propagation.
Does it fully capture your scenario?

The scenario you describe is a simple one where one transmitter is
heard at two receivers. The calculation of the interference at a
single receiver from two discrete sources or one discrete source and a
host of interfering sources is obviously more complex.

Best solution? Turn on your radio and actually copy code with pencil and paper.

The code reader is fair with machine generated code in a clear channel
situation. It is poor with human controlled character timing and QRM and QRN.

I don't think I could learn to copy CW by watching a small LCD!

The Human ear.

It doesn't need batteries, can provide reliable copy when band conditions
are bad, or the sender can't send well. All you need is a pencil and
paper for hard copy.

It takes a little work to get good at the Ear method, but no one has ever
has any problems learning it unless they're sick, lame, or Lazy.

4722. TOOL FOR CUTTING EARTH & BURYING RADIALS ????

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-28 00:13:54 UTC
From: solidgoldZZZ@optonline.net
Message-ID: <451b12b1.1158937@news.optonline.net>
Source record: 52209

A friend of mine told me that at Dayton, over the past few years, he has seen a tool that looks like a lineoleum knife with a small tube welded onto it for cutting the earth and burying an antenna radial at the same time. You feed the wire through the tube, and as the tool cuts the earth, it dispenses and buries the wire. Has anyone seen this tool, and who makes it ??? Where can I buy one ???

Richard

I am not surprised with your result after having used various MS
compilers over the years. Do you have any idea what the real
differences were in the libraries? Borland C always seemed better, more
robust at error handling, and more accurate.

I noticed similar problems back in the late 80's with MS C, but never
really needed the precision, and work pressure being what it was....

Yep, that's about right. I cut it at 51 x2 = 102 feet but I used
insulated wire...so if I want to bring down the antenna to correct it, I
should remove about 18 inches per side, right?

Pretend, for a minute, that I am NOT an antenna "purist" (not too hard a
task, you say?)

...Do I want to go out and correct it or just let the ATU compensate?

Hi Tom,

I can only speculate from my experience coding various expansion series before the 8087 was generally available. My guess is they went with the first one in a cookbook - Newton's method comes to mind, but that is of vague recollection. It is generally useful as a first pass method. M$ became extinct in the Pascal marketplace soon after. I also moved on into C++ in the late 80s (a local company here wrote one of the first cross-compilers).

The M$ crowd thought they would take that one on too. In 1990 they asked me to come in and give classes. What a fiasco. The first question was how to do inline code. They were arrogant to the point of wanting to call "their" version C++++ with the +s stacked in pairs to produce #. Can anyone guess how long C-sharp took to get to market?

The scenario I consider is a number of transmitters and receivers that communicate with eachother. Therefore, the free space model does work, but each non-intended receiver receives the interfering power. However, in my case transmitters will receive requests from receivers that can be in any direction and thus I believe omnidirectional antennas may be more appropriate. Omnidirectional antennas allow us to receive and transmit in all directions equally. Therefore, there isn't a need for directivity and the use of directional antennas. Are 25 dB omnidirectional antennas realistic for 802.16a?

You should rattle your head to get your memory straight.

Who brought "shame" to amateur radio? W8JI for claiming nonsense that current along the antenna loading coil is constant and Art for patenting Yagi Reflector being shorter than driven element, or those who objected to fallacies being propagated on the waves of the RRAA?

Looks like your logic is a little "converted" or inverted or deflected.

Keep it up, you are way ahead of us :-)

The length of feedline(s) may be constant, but the losses in the
feedline(s) depend on VSWR, and nothing you can do with an ATU changes
the loss in feedline(s) beyond the ATU.

I note that you have figured that the dipole is 3' too long, that is
about 3% too long, but the antenna resonance appears about 6% low at
14MHz. Are those two pieces of information consistent?

Owen,

I get about 4% at 14 MHz, 3.5% at 7 MHz, next to zero on 80M...these are
all relative to the low CW portion of the band where I "live".

I understand your point. VSWR at the XMTR as lowered by the ATU makes
the transmitter happy but the antenna may not be happy or as efficient.

Being a pragmatist and the wet season about to arrive, I just want a
handle on whether, all things considered, it is worthwile to shorten the
antenna or leave it alone.

I've got to start using EZNEC.
:)

>Should they be consistent?

Yes, the length of open wire section of the feedline influences the
frequencies at which the RG8 VSWR is low, near as much as the dipole
itself.

The band where the "tuning" of the radiator and openwire line section
(together) is most critical is 80m, the optimal bandwidth (from a feed
loss point of view) is narrowest, and has the steepest sides.

However, the place where the VSWR looking into your RG8 is most
predictable is at 20m (typically 14.2MHz) where the common form of the
G5RV should have a three half waves resonant dipole and half wave
electrical open wire section. The Z at the dipole centre will be
around 90+j0, and if the loss on the open wire line is low, the Z into
it will be 90+j0, for a VSWR on the RG8 of just under 2, a little
lower at the tx end.

If you were to find that the VSWR minimises higher or lower than 14.2,
it is a sign that the combination of the dipole length and open wire
section are too long or too short.

If you objective was resonance of the dipole + open wire section at
14.2 (and I now understand that is not your objective), you would be
6% low with your stated observations.

If you are happy with the location of the VSWR dip on 80m, leave it
all alone because the VSWR dip results in the least losses in your
RG8, and if that is of significant length, then the additional losses
are significant. Most other bands are less sensitive than 80m, but
note that a G5RV is not efficient on "all" bands, and so should not

qualify as an all band antenna.

Using the freespace model will, in most cases, give an very optimistic
result; unless there is a true optical path between both antennas and they
are both very well clear of the ground and other obstructions.

It sounds like omni directional is what you want, and 25dBi gain is
unrealistic, stick with 6 to 8 dBi max for a very good omni.

Regards
Jeff

This isn't what you asked, but you might consider not burying the radials at all unless you have to. Radials on top of the ground are slightly more efficient because the RF energy does not have to penetrate the lossy earth to reach the radials. If you have grass, just lay the radials down and tack them in place with some homemade staples. In a few months the grass will grow over them and you'll never see them again.

Of course, if you're putting them on top of bare earth, you may have to bury them for safety reasons.

Just a thought.

Bill, W6WRT

I can second that method from personal experience. When I installed my ground mounted Hustler 5-BTV I laid the 72 radials on top of the ground (this happened to be in the dead of winter with very little grass height) and held them in place with 1 1/2" "fence staples" pushed into the earth. I then covered them lightly with some soil and next summer they were well beneath the grass height and no issues with the lawn mower.

Pictures (before & after) of the entire installation here at this page.

I would think that cutting through grass roots plus the soil would
require soft soil and even then I would suspect a fair amount of force
would be required. Plus trying to maintain a decent cutting edge might
be a problem.

I used a different approach. I installed an additional cutting blade
(to increase width) on a gas powered lawn edger then used it to cut
very small trenches about 2-3 inches deep. Then I just placed the wire
in the trenches. It worked well - even in hard dry soil - but you'll
get good a dirty doing the job. Throws dirt right up into your face so
be sure to ware eye protection.

4759. Dressler ARA 100HDX NIB $450

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-28 23:14:41 UTC
From: safetypro <bfdp1@msn.com>
Message-ID: <1159485281.444385.128640@h48g2000cwc.googlegroups.com>
Source record: 52146

Dressler NIB (still sealed in shipping box) $450 shipped ARA100HDX

covers 40 kHz to 100 MHz and is designed for the interception of weak signals even in the presence of strong broadcast station signals. The ARA 100HDX is a alternative for those who do not have the space for a traditional outside wire antenna. It is compact and unobtrusive. The output impedance of the antenna is always 50-75 ohms, independent of frequency. This allows efficient connection directly to the receiver without an additional antenna tuner. The ARA100HDX will not overdrive most portables.

Universal sells for $550

25 years? Probably about the same, since repeaters had been around
at least 10 years by then. You could by a repeater over the counter
with tone squelch, and several other toys built in, so they were no more
complicated than a 2 meter handheld. My high school Amateur radio club
built a two meter repeater of of Motorola and GE strips, homebrew powers
supplies, diplexer, and timers in the late '60s. What is the big deal,
unless you have multiple sites and voting receivers? We were just a
bunch of RF crazy teenagers with less than $50 to spend, and we wanted
to build a repeater. A few months later we were given a surplus WE Touch
TOne decoder module, and added a phone patch.

Like everything else the club did, we raised the funds by repairing
old electronics and selling it to buy the parts we needed for the next
project. the only new piece of equipment we ever purchases was a HW-16,
in kit form. BTW, CW was the least used form of communications from the
club's station. they could do that at home, but we had some nice
antennas, the two meter repeater, and several full coverage HF rigs.

I just ran a few analyses which are relevant to this discussion. They were done with EZNEC/4 using an NEC-4 calculating engine (although NEC-2 will give the same results), using MININEC-type ground to simulate a lossless ground system, and with surface wave included. The antenna is a 0.25 wavelength high vertical. The intent was to look at the vertical pattern characteristics at various distances.

Before discussing the results, let me point out that radiation very close to a vertical antenna is maximum at the horizon, as Rich has said. However, the field propagating in proximity with the ground (the surface wave) gets attenuated with distance much more rapidly than the normal attenuation of a wave in free space (or the sky wave, discussed shortly), which is attenuated only because it expands to cover an increasing area with increasing distance. At a distance beyond which the surface wave has decayed to a negligible value, the remaining field is known as the sky wave. This has the pattern characteristics you'll see with EZNEC (unless using EZNEC pro with ground wave enabled) or NEC without ground wave enabled. Because of ground reflection, the sky wave has zero amplitude at an elevation angle of zero except for perfectly conducting ground. For typical ground conditions and in the HF range, the maximum field strength occurs at an elevation angle on the order of 20 degrees. Remember, this is the sky wave, which is what's left beyond the distance at which the surface wave has been attenuated to essentially zero.

The rate at which the surface wave is attenuated with distance is a function of ground conductivity, and a very strong function of frequency. That's why AM broadcasters successfully use surface wave propagation, while it's of little use to amateurs operating at HF and above. Rich's original posting showed how some of the surface wave from a broadcast station can (presumably) even reach far enough for the Earth's curvature to allow it to escape and reach the ionosphere for longer distance communication. As the following results will show, this doesn't happen at HF and above.

Here are results of the analyses.

The initial runs were at 1 MHz, which has been the focus of Rich's comments on this thread. The reported field strength includes the entire field, or in other words, the sum of the sky and surface waves.

At 1 km, with either average or very poor soil, the elevation pattern shows a monotonic decrease as you go up in elevation, like in the plots referenced in earlier postings and resembling the plot of the pattern over perfect ground. Changing the ground type attenuates both the sky and surface waves (although not necessarily by the same amount), which

tends to reduce the dependence of pattern shape on ground characteristics. So the same general pattern shape occurs with a range of soil types.

However, the pattern shape is profoundly affected by both distance and frequency because both these determine the amount of surface wave attenuation. For example, with average ground at 10 km (rather than 1 km) from the antenna and 1 MHz, the field strength is relatively high at zero degrees elevation, and drops as the elevation angle increases, as it does at 1 km. But at about 2 degrees it hits a minimum and begins increasing again, reaching a maximum at about 20 degrees elevation, which is the angle of maximum sky wave. At that point, the field strength is about 1.24 times (about 1.9 dB greater than) the field strength at zero degrees elevation. This is because the surface wave is attenuated much more rapidly with distance than the sky wave, and at 10 km the surface wave has already decayed to less than the sky wave field strength. At 100 km, the ratio of sky to surface wave (that is, field strength at 20 degree elevation compared to zero degrees) is 13.6 dB, because of course the surface wave has decayed a great deal more.

At 3 MHz, the attenuation of the surface wave is much more dramatic. Just 1 km from the antenna over average ground, the field strength *increases* monotonically (at least above 0.1 degree, which is the lowest I checked) as the elevation angle increases, until it reaches the sky wave peak at about 24 degrees. At that angle, the field strength is more than 40 dB greater than the strength at the horizon (which is the remaining surface wave). At 10 km, the field strength at 24 degrees is more than 60 dB stronger than that at the horizon. And of course, this effect becomes stronger with increasing frequency and distance.

So even at 10 km distance from the antenna at 3 MHz over average ground, the sky wave is more than 60 dB stronger than the surface wave. The difference becomes greater at higher frequencies and greater distances. This is why the surface wave is of little practical interest to most amateurs. And it's why you'll never see the wonderful low-angle ionospheric propagation effects Rich predicted in his original posting on this thread.

The EZNEC/4 results are just what we should expect, given a knowledge of how the surface wave and sky wave are attenuated with distance.

I caution people to take care in extrapolating propagation or antenna performance results at AM broadcast frequencies to the higher frequencies more commonly used by amateurs. If done carelessly, it can lead you to reach some pretty seriously wrong conclusions.

Ah, the perennial cry of the pseudoscientist. I am misunderstood! My idea will change the WORLD.

But then, you offer no real evidence. You're basically giving a supernatural explanation for the operation of the antenna. The RF current flow is a ghost.. it's a haunted antenna. What measurements do you have to show that your grounding system does what you say?

A very, very inefficient antenna can get you good signal reports. You're trying to get people to send you cash for your haunted antenna, so you won't do real measurements. You don't really know how much power is being radiated by this antenna, and never will we, unless we send you money.

Dan

Don't know about whether it saved any lives or not, but I once took a very
important NOTAM (Notice to Airman) on CW from a guy in the Aleutians in the
days following the 1964 quake and put it on the proper teletype circuits
for him.

His airport's altitude was changing so that charts and other info were
inaccurate.

Nice strawman. The pixels form a full complete picture. Beeps are just
beeps. One dimensional. That they form a recognizable pattern does not
make them more. Humans are highly visual creatures. I have listened to
code for years. Being able to make out a few letters does nothing for
me.

It's just plain dull.

Cecil, efficiency depends on what your objectives are
The yagi antennas objective is to obtain a radiation beam of gain
compared
to radiation else where. What is wanted is a radiation lobe that one
can use to direct communication. ..rThe yagi achieves the object of
producing a lobe which has a higher gain than other lobes that the yagi
produces.(A higher ratio) The yagi achieves its object by producing
this
main lobe but at what cost? If we look at pattern volume as reflecting
as energy applied to the yagi we must compare that volume with the
whole pattern volume. This means comparing the volume of the upper
lobes, the side lobes, the rear lobe and of course the vertical lobe to
the main lobe. Any cursury look at a three D radiation pattern will
immediately see that the main lobe is less than 50 % of the total
radiation pattern
Let us look at a common dipole with a reflector, the planar view of
radiation which ignores radiation outside the plane is a figure 8 where
the addition of a reflector does nothing to enhance increased forward
radiation so immidiately we can say that the forward lobe achieves what
is termed a major lobe plus other forward lobes outside of the main
lobe
where as the radiation to the rear achieves nothing that enhances the
forward main lobe. So just comparing the forward and the rear lobe we
have only achieved 50 per cent of our object
and this is not counting other losses. Now you may disagree with the
objective of a yagi beam and I understand that may be the case.
Hopefully the above answers your request to
define efficiency as I was with respect to the yagi antenna. I think
the above pretty much explains what I stated in the initial post tho it
appears that some read inbetween the lines to read what they wanted to
read as a diversionary tactic and there is not much anybody can do
about that. One really has to ask themselves the question that if an
antenna came on the market with only one main lobe would they buy it

One has to be carefull when talking about angles of propagation and how the antennas fit the mode and angles.

During the sunspot minima, the atmosphere shrinks, layers get more dense and lower, compressed. Lower angles are favored. Also at the beginning of higer bands openings low angles prevail, later on, in the middle of the opening to particular area, the higher angles prevail. Having stacked antennas, or combination of verticals and horizontals, one can observe the various modes and how the antennas take advantage of them.

I have seen the effects and described them in my CQ article, see http://members.aol.com/ve3bmv/bmvpropagation.htm

On low bands there are situations (mostly around sunrise) when high angle prevail (low Inv Vee) and verticals (and beverages) with low angle pattern can't even hear the station.

Also the ground conditions play big role in the performance especially of verticals. Put them up at the salty beach, they are killers (loooow angles enhanced). Put them up with lousy soil (clay) they don't work well.

Out of curiosity, did you

a) not read
b) not understand, or
c) not believe

what I posted about the fraction of power in a Yagi's minor lobes?

A cursory look at a 3D pattern is probably one of the least reliable ways to determine anything quantitative about an antenna pattern. By choosing the scale (e.g., field strength, power density, linear dB, ARRL-scale dB), you can make the relative sizes of the lobes just about anything you'd like and lead the casual observer to the conclusion of your choice(*). But why bother trying to divine a value from a 3D pattern, when it's so simple to numerically show that the power in the lobes is insignificant?

(*) One of the slides in the "Antenna Basics" talk I've given at many hamfests shows several very different directional patterns, and I ask the audience which one is the most desirable. After the votes are in, I reveal that they're all the same antenna, just drawn to different common and legitimate scales.

W7EL wrote:

>>So even at 10 km distance from the antenna at 3 MHz over average ground, the sky wave is more than 60 dB stronger than the surface wave. The difference becomes greater at higher frequencies and greater distances. This is why the surface wave is of little practical interest to most amateurs. And it's why you'll never see the wonderful low-angle ionospheric propagation effects Rich predicted in his original posting on this thread.<<

Surface wave applies mostly to day time propagation at AM band and 160. When we propagate during the night at low bands, horizontal (high angle) antennas give stronger signals within about 500 -700 miles. Beyond that the low angles (surface?) rule, except in some high angle propagation at sunrise. Those who work long pass and far DX on 160 know that verticals (low angle) dominate (while being "inefficient" at closer distances at the same time). Being at the salty beach front enhances the signals and low angles by about 10 - 15 dB. Can we call those angles "surface"?

The point is that propagation modes are very finicky and vary, making blank statements about attenuation some times doesn't jive. Way back when scientwists figured out that no way signals on HF can go large distances, because of calculated dispersion etc. we (OK, our forefathers) were given "useless" HF bands to play with.

>>The EZNEC/4 results are just what we should expect, given a knowledge of how the surface wave and sky wave are attenuated with distance.<<

That is somewhat valid within close proximity (one "hop").
EZNECs do not incorporate propagation mechanisms. They are usefull to calculate the pattern of particular antena, but how that fits the propagation and delivering the signal to the target, is another story. Most people trivilialize the propagation and assume that signals nicely bounce between the ionosphere and earth, which in reality gets way out of those distorted pictures of earth-ionosphere in the books.
http://members.aol.com/ve3bmv/bmvpropagation.htm

>>I caution people to take care in extrapolating propagation or antenna performance results at AM broadcast frequencies to the higher frequencies more commonly used by amateurs. If done carelessly, it can lead you to reach some pretty seriously wrong conclusions.<<

That applies also when trying to use EZNECs and other antenna modeling software in predicting propagation and how the signals get to the other end. The beautifull and unknown thing is that propagation can play games with paths of signals and unless one has variety of antennas that can "see" the

angles and modes, you would never know.

>>Roy Lewallen, W7EL<<

Just an example: I was at Cape Hatteras on 10m in a contest. Band started to open and ZS6EZ told me I was the only NA station he was hearing. Was that "dead" surface wave? It was definitely low angle from my pair of verticals stuck in the sand and running barefoot. Big multi/multis with their stacked beams and kWs were not audible, and they CQ even on the dead band. The point is that I was "manufacturing" signal at low angle, that according to calculations should have been "expired".
Another one was when operating 160m from W8LRL. There was short opening to Japan. Wal has different antennas for that area. Vertical circle 8 el. array, EWE, regular Beverage, phased Beverages and 3.5 wave long Beverage. JAs were audible only on 3.5 wave one, which has the lowest angle than any other antennas.
Obviously, low angles are not useless for DX as above calculations might imply.

W8JI way back argued with me that there is no way there could be high angle propagation from long haul DX on 160, or skewed path. (Now he is the guru on the subject :-) At he sunrise, low (high angle) inverted Vee can run circles around verticals and Beverages. The difference could be dramatic, like S7 vs. no signal.
I discovered way back than one has never enough of antennas, especially for serious contesters, if they want to take advantage of different propagation modes and angles/polarizations.

What a shame that we all have to agree on how to be a ham. Oh, wait -- we
don't.

Effective right now, everything legal that anybody wants to do for their
personal enter-ham-tainment (don't try to look it up) is OK with me.

I did not understand your logic.
Front to back means nothing in terms of energy containment
The measerment is a ratio not a quantity
It also is a ratio only for a given plane and does not account for
anything outside that plane.
Have I stated anything wrong there?

Point out the error of my ways starting with a simple dipole. Does any
additional element to the array revert the radiation from the rear
direction so that it is additive to the forward directive radiation of
the main lobe? If so what percentage of the rearward radiation in the
rear hemisphere,,(ot a planar amount) ? The question is to you Roy to
answer for a one on one,It would help if you gave an actual percentage
instead of a "major fraction" which you stated before

And if you don't understand then just drop the thread as it has gone
on way to long with relatively little specifics with respect to the
original post

I do not remember seeing any numerical answer ,was it specific and
relative to the
contained energy in the primary lobe because that is what I was looking
for ?
What was the actual percentage that you arrived at?

>
> (*) One of the slides in the "Antenna Basics" talk I've given at many

Roy
the actual scale doesn't matter one iota on a given pattern with
respect to my question !
To compare different patterns one must have a common denominator such
as scale,
to do otherwise is an attempt to deceive. You also use the word
"desirable"and my connoctation of that is a major lobe and nothing else
whereas some may look for other characteristics. Did the group come to
a consensus as to what was desirable? Some may want to hear what is
said behind their backs!

I thought your interest was in the amount of power contained in lobes other than the main lobe of a Yagi. My posting showed a simple way to relate front to back ratio, which is commonly known for many Yagis, to the fraction of power in secondary lobes, which is not.

> Point out the error of my ways starting with a simple dipole. Does any
> additional element to the array revert the radiation from the rear

Of course.

> If so what percentage of the rearward radiation in the
> rear hemisphere,,(ot a planar amount) ? The question is to you Roy to
> answer for a one on one,It would help if you gave an actual percentage
> instead of a "major fraction" which you stated before

In my earlier posting I apparently overestimated your ability to do what I thought was a simple calculation. So I'll do it for you so you can have a number.

Since there's no "typical" Yagi, I presented one which most people would consider to be worse than average -- one having only a 6 dB front/back ratio. I also assumed for a starting point that the shape of the rear lobe (that is, beamwidth and height) is the same as the front lobe. The first calculation is to determine just what the ratio is of the powers in the front and rear lobe. The answer is 4:1. That is, the front lobe contains four times the power of the rear lobe. Since you seem to be interested in energy rather than power, simply consider the amount of energy each radiates in some amount of time: each second or other unit of time, the forward lobe radiates four times the energy of the rear lobe.

What this says is that if you manage to get all the reverse-lobe power (or energy, if you prefer) into the front lobe, without any change in the front lobe's shape, you'd increase the gain just about exactly 1 dB. If you end up fattening it, you'll lose some or all of that gain.

So there are some numbers for you. You'll have to do a bit of estimating if the rear lobe is fatter or skinnier than the front lobe, but now you have a number to start from.

Or let's say that the front/back is 10 dB instead of 6, a more typical number for a Yagi. With the same criterion of similar lobe shapes, the power ratio for the front and rear lobes is 10:1. So if you got all that rear lobe power or energy into the front lobe without changing its shape, you'd gain a whopping 0.4 dB. If you had two equal rear lobes, both 10 dB below the front lobe, and both of the same shape as the front lobe, the power ratio of the front to all rear lobes would be 5:1, and you'd be able to increase your forward gain by 0.8 dB if you got all that rear power into the front lobe without changing its shape.

So there's your actual percentage -- around 25% for a very poor Yagi, and around 10 - 20% for a fair-to-middlin' one. From which you could gain about a dB by very hard work in getting all that rear lobe power into the front lobe(*).

If you question any of the calculations, I'll be glad to show how I converted ratios to dB and vice-versa, although you should be able to find this in many publications, as well as on the web. Or you can continue drawing your conclusions from cursory looks at 3D plots. Your choice.

> And if you don't understand then just drop the thread as it has gone
> on way to long with relatively little specifics with respect to the
> original post

I'm afraid I do understand, but it's a good idea anyway.

(*) Being an engineer, I didn't include placebo effect gain in the calculations. After a lot of hard work squeezing every last bit of power into that front lobe, the signals are going to *seem* a lot stronger, and the reports sure to be better.

Before I go to the trouble of putting up a rhombic, I've been using NEC to get an idea of the gain, radiation angle etc for various leg lengths. It all looks very promising on the computer but I'd be interested in real-world experiences. For example, how well does the real antenna approach the PC simulation when various factors like wire sag, uneven ground, presence of trees and shrubbery?

Hi Alan,

Rhombics were the stars of antenna developement in the late 1920s for
RCA. For very long wavelengths, certainly few other practical designs
could achieve the same gains. For shorter wavelengths, other designs
replaced the Rhombic (poor return on real estate in comparison).

If the wire sags such that most of it is on the ground, you suffer.
This is a judgement call otherwise and sag is quite within the ability
to model if judgement demands.

The presences of trees and shrubbery is something all designs suffer.
Unless you are speaking of an antenna in a forest, the Rhombic would
probably do quite well (after all, it is wavelengths long, as are few
trees) until you start getting into short wavelengths.

Rhombics are few and far between these days. Reasons are principally
wavelength based in comparison to available real estate. Few have the
real estate for long wavelengths. If you are working at a short
wavelength, there is a better design to do the same job.

I guess that is why there are 20 definitions for "efficiency"
in the IEEE Dictionary. One needs to state one's definition
of "efficiency" at the beginning of the discussion to avoid
confusion with all the other possible definitions. For instance,
Power Company EEs have a different definition of "power" than
do physicists, politicians, and priests.

Alan, the rhombic is a relatively inefficient antenna that 'may' give you significant gain in point-to-point service, which is why it was popular in the early days of commercial and governmental radio services...
For ham radio it is less attractive due to the real estate it requres, due to the cost of the poles (it usually needs to be supported at a number of points along each leg to stop excessive whipping in the wind)... Less attractive because it requires retuning of the matching unit for small changes in frequency...Less attractive because it confines your communications to a narrow angular beam...
Being a long ways from the other population centers of the world you may be in a situation where you find it effective... Most of us don't...

Update:

Well, yes, the antenna was too long (not too short). I decided to lower
the antenna and shorten each leg by 18 inches. Now it's back up about
45 feet, sloping to about 25 feet. (No change from before.)

Now, SWR dips are at 3.610, 6.710 and 13.580 MHz.

These are not what was expected. Oddly, on 40M SWR dip went further
away from the band edge (as if dipole was lengthened).
I did not change the 300 ohm window line (at 31 feet).

From what I've read here and elsewhere, I should note 80 and 20M
performance as primary considerations.

I'm a little nervous about shortening it further.

I am not interested in front to back for what I am looking for but this
4:1 has my interest
What does it represent and how did you get it? The rear usually has
more than one lobe
and the reflector ndestructs or deflects the energy to 90 degrees of

impact. But that 4:1
figure where does it come from?

I'll bet your minimum SWR points are not purely resistive.
Any chance of borrowing an MFJ-259B and reporting the
purely resistive points?

If that's the 300 ohm ladder line with heavy insulation,
it has a VF around 0.8 and Owen's feedline calculator at:

http://www.vk1od.net/tl/tllc.php

says that 1/2WL at 14.2 MHz is ~27.7 feet. If you shorten
your 300 ohm section by about 3 feet, you will have close
to a standard G5RV with the minimum SWR points where they
should be.

I have to disagree with some of your statements Denny..

I used rhombic's over the years and they can be very efficient if properly fed they do not require constant tuning. Their bandwidth can be quit good. and you only need 4 pole if properly installed. I use large rhombics before that went through 100 plus M.P.H. winds without any problems. They are relatively expensive to install properly . the matching situation can be handled easily with Baluns or open wire feeders. only problem you may have is comming up with the terminating resistor.. Their kinda hard to find cheaply today.

Remember that they are very good point to point radiators and rx antennas if you calculate things right for your desired path .. they also can provide multi lobes to favored directions if desired. and that is somewhat dependent on your operating Frequency and the size of your Rhombic.

If I had the room I'd consider rhombics for Sure.. W6AM used them for years and as one who worked that station from many places on this earth I can tell you he was never the weakest signal on any band.

I used a rhombic in the 70s while on contract TDY at Hill AFB, Utah [AGA5HI - USAF MARS].

It was point to point from Utah to SE Asia [Vietnam War] and approximately 5 wavelengths per leg on 19 MHz and about 40 feet high [guess ... near top of telephone poles].

It supported the SE Asia phone patch net [USAF MARS]. The USAF had LOTS of land for the antenna.

We later switched to a Log Periodic as more versatile.

There are already words defined to mean the antenna parameters you are talking about. I suggest you use these instead of defining yur own so people will know what you are talking about. Antenna patterns are expressed in db. This means they are logarthmicly compressed. IF they were displayed linearly the sidelobes would would be invisible on the graph. Again. ad nauseum, there is no significant power in a sidelobe of any reasonably designed yagi antenna..

Dave, that sounds very suspicious considering my ground school instructor's 1962 display of a then-old Santa Barbara, CA, half-hour TTY Wx report (then required by Commerce Dept.). SBA (ID of Santa Barbara), like all other weather stations at airports, were required to post their local Wx and airport conditions every half hour. SBA is on the Pacific coast and subject to rapid variations of weather. If weather changes more rapidly than that, weather stations were required to post extra in-between-scheduled-times reports.

One day, after having fog entering and leaving SBA often, the operator of the TTY sent: "THE FOG SHE COMES IN THE FOG SHE GOES OUT." :-)

The ground school class at VNY was presented with a glassine-protected TTY copy of the Wx message that must have been old at that time (the cheap TTY paper was already turning yellow). Got a good laugh from the class.

In 1964 (which is 42 years ago), the weather stations had their own network over leased telephone lines. At least in the 48 contiguous states. Whether or not Alaska was tied in with

manual telegraphy (radio or wirelines) I can't confirm...nor do I think it important since I know it was NOT via amateur bands.

NOTAMs take many shapes but back 40+ years ago, the FAA handled them and saw to their distribution at airports. Most were press-printed but some current ones were sent by TTY. That was in times before NOAA.

Adding a director or reflector in the plane of a dipole can make it nearly unidirectional. It will have forward gain over the dipole alone. Adding more directors can increase forward gain. Losses of the radiator and parasitic ellements to heat in them can be made small and antenna efficiency high.

> What does it represent

I can't think how I can state it any more clearly than I did in the last sentence of the text just above which you quoted.

and how did you get it?

When dealing with a power ratio, dB = 10 * log(ratio). Solving for ratio:

ratio = 10^(dB/10)

Here's where you'll probably need to get out that pocket calculator. dB is 6 (see above text), so ratio = 10^(0.6) ~ 4.

Conversion between ratios and dB is a skill that anyone interested in antennas should develop. I had assumed that it was part of the knowledge required to pass a general class amateur exam, but apparently I was mistaken. If the calculator operations are too complex for you, get a chart of conversion factors which have already been calculated.

> The rear usually has
> more than one lobe

True. See the remainder of my previous posting for a discussion of this.

> and the reflector ndestructs or deflects the energy to 90 degrees of
> impact.

That's more nonsense. You'd develop a much better understanding of antennas (or any physical system) by developing and learning to apply some basic math skills than by dreaming up alternate explanations for well-known physical phenomena.

I don't believe I can help you any more -- if indeed I've helped you at all --, and think (or at least hope) that most other readers have

understood what I'm saying. So I'll bow out here.

Terman treats decibels on page 8 of the 1955 third edition of "Electronic and Radio Engineering".

The value of the decibel is 10 log of the power ratio.

When the ratio of the powers is 4, the decibel value is 6. This 6 dB value applies among other things to doubling the distance between a transmitting and receiving antenna. Half as many volts will be induced in the receiver and will result in half as many amps. This is 1/4 the power induced at half the distance between antennas..This may be expressed as a positive power ratio of 4 to 1, or 6 dB.

Best regards, Richard Harrison, KB5WZI

I had to ask rather than assume. My inclination where it came from
which you didn't say was that since the field produced by an actual
antenna is twice as great as the field produced by the isotropic
antenna the gain RATIO is two and the power gain is 2 squared which is
4. this means that to produce the same field strength at the same
distance, four times as much power would have to be supplied to an
isotropic radiator as to the actual antenna under consideration. But as
I stated many times RATIO as you are using it has not interest to me as
it is not relevant.
What you are doing is based on a RATIO at a given plane and that RATIO
changes with the plane examined. That is why the yagi is termed a
planar array In other words a reflector is used to affect a single
plane of radiation it is not all encompassing of the total rear
radiation. On top of all that the plane chosen is along the plane of
the main lobe only and does not in anyway include the ratio of the
second lobe to the rear or any nulls that are made. The rear radiation
fields is no way a mirror image of the forward radiated field. You are
supplying a conventional answer to a convential question which revolves
around a single plane where I am speaking of the total radiation field.
You can't keep trotting out the conventional answer to the question
that you want to be posed. I am sure glad I didn't guess where you were
getting the figure 4 from otherwise the thread would have been 200
posts long plus a lot of accusations as to who said what.Get back to
basics and stop trying to section the field of a dipole to make it
easier to simplify for newcomers, it does not represent factually
everything.
it is just a means to an end. without involvement in the toital "wave
and fields" subject
As I have oft times stated I am looking at the whole pattern in three
dimensional form and you keep trotting out answers based on a two
dimensional format

then i would suggest learning some of the nitty gritty details of a program
like nec and figure out how to integrate it's field values over the 3d
surface and sort out the values you are interested in. no one here will do
that for you since it is normally not of interest in amateur antenna design.
we all understand how to evaluate the performance of antennas for our
'normal' uses in terms of gain and f/b ratio and how to read those 2d slices
to evaluate side lobes for our 'normal' uses. as you have stated it your
desire is not a normal one, you have special requirements which will require

a special solution that is not readily available for amateur antennas....
maybe that data is available for large satellite or deep space dishes where
they worry about extreme details of side lobe power and noise temperatures,
but not for hf ham use with normal antennas.

Art,

The same process in any plane reveals the same net result: you are not going to achieve any more "efficiency" than that already offered by a Yagi.

In fact, your design probably suffers extensively with regard to "efficiency."

But no one knows this mystery design, do they? Sorry, but Fritz has already cornered the market on flim-flam. He has probably been more efficient about it too (if measured in sucker deposits).

Don`t worry. I`ve erected many rhombics. They were all astisfactory and very forgiving. Most were about 4 or 5 wavelengths on a side (leg) and they were about twice as long as wide. They all worked well over a wide range of frequencies. It`s just a terminated transmission line with a big spread in the middle so it will radiate. Matching is a cinch.

Best regards, Richard Harrison, KB5WZI

Art,

As I re-consider this statement, I don't believe you at all. The earliest solutions to your "problem" were satisfied by stacked yagis. They also answer what you complain of above as well. Bay arrangements of yagis go even further. As they are skeletal versions of a massive dipole array against a screen, all are solutions that are merely the natural consequence of massive duplication and constructive phase shift.

This stuff has been around for half a century or more and you have yet to reveal anything new, much less a method that transcends existing knowledge. If you had more experience in using modelers, and examining the history of antenna design, then you could confidently make the statement above. However, nothing in your correspondence even reveals you understand the fundamentals beyond parroting phrases cut and paste from other sources.

>lobe where as the radiation to the rear achieves nothing that enhances
>the forward main lobe.

So the most efficient antenna is the isotropic, because its radiating
volume is a sphere. Next would be a dipole, then a vertical, and then
a yagi with just 1 parasitic element, and getting worse as you add
elements, because each element is shaving a bit off the volume.

Correct?

I can vouch for that. In 1961 I was stationed at Dharhan AFB, Saudi Arabia, and operated many times from HZ1AB there -- at the time the only licensed amateur radio station in Saudi not connected with the royal family.

We used a Collins exciter driving a heavily modified BC-610 to a terminated rhombic aimed down the eastern seaboard of the US. We had no trouble reaching the States (and hearing 1,000s of DX-ers wanting to talk to us).

OTOH, military links I took care of using KWS-1s into 6-element rotatable "beams" didn't do as well.

>I'm a little nervous about shortening it further.

I have explained to you several times that the length of the radiator
and the open wire section act together to influence the impedance
presented at the coax to open wire junction.

I asked if you had measured both elements and if you had considered the velocity factor (for your actual line) in those measurements, but you did not reply, and you have not reported the length of the open wire line. The surest way is to measure the velocity factor, calculate the correct length and accurately cut to that length.

The common G5RV has dipole's second series resonance at 14.2 and the open wire line an electrical half wave at 14.2, which will present a resistive load of somewhere 80 to 90 ohms at the coax to openwire junction, and you will observe a VSWR minimum on the coax at that frequency (even at the tx end of the coax line). (Of course if you do something silly like use a 50 ohm VSWR meter in a 75 ohms coax line, you aren't making valid VSWR observations.)

Remember the rule: measure twice, cut once.

It can't be all that hard, can it.

Owen

PS: I noted your throw away comment that time is of the essence, the wet season is coming. Have you noted the recent comments on performance of wet ladder line. Depending on the construction, your 300 ohm line might be subject to similar degradation, and your "optimised" configuration might not be optimised when the feedline is wet.

Although the term "efficiency" seems to be used with gay abandon in
this place, the rhombic is not close to 100% efficient, a portion of
the transmitter power (approaching 50%) is dissipated in a
non-radiating loss.

That loss does not have an adverse impact on the gain in the desired
direction, and so it should not be regarded as a disadvantage of
itself.

It is true that a vertical monopole antenna will have a larger total
footprint of coverage than a yagi. If the earth was evenly coated with
ham radio operators I could probably make more contacts using a
vertical monopole than I could a yagi that could not be rotated.

The rhombic can deliver you a frequency agile antenna with gain, and low angle major lobe if of sufficient length and at sufficient height. Side lobes are not pretty, space requirements are huge at HF and the antenna is not readily rotatable, construction is simple, but serious.

You are on hectares (doesn't sound as good as acres, does it?). Space is not a big issue, and every ham that can accomodate a good size rhombic should have one (or more) as a talking point. You could deal with the fixed heading disadvantage two ways: place the shack in the middle of the rhombic and switch feed / load ends, or go the whole hog and erect a set of rhombics to cover your desired / preferred paths.

Keeping in mind your exposure to high winds and snow (ice loading), the construction needs to be robust. If for example you want coverage down to 20m you should be aiming legs of close to 100m. Sag of 5% of span is easily accomodated if the end heights are at 20m of more, but becomes a problem as you lower the end height much. You could model the effect of the combination of sag and low end height in NEC by breaking the leg wires into several sections following the approximate catenary (or parabola for ease). I haven't done it, but I suspect uncertainty about the ground conditions and ground profile will introduce more model error than modest sag.

I believe you are correct.
If you understand the question posted over a 100 posts ago why is it
that others are stumbling.
I could not figure out how to determine the volume mathematically so I
took the model making route which confirms the poor efficiency of the
yagi. What blows my mind is the assertion that the major lobe is a
large fraction of the total volume whatever a large fraction really
means (no hints given by the poster) plus the idea that volume outside
the main lobe is miniscule,.Seems like memorisation of required answers
is the way to go with amateur radio at the moment. Thinking from first
principles obviously not required just give an answer that you want to
give regardless what the question was and then blame the poster because
he didn't pose the correct question for which the answer was well
suited.
If you can't provide an answer then change the subject and then discuss
that
Well I am glad somebody read that first post for what it said not for
what most wanted to read. I feel a lot better now

Many use "QSO" as a signifier of a "Voice" contact as well, so "why" couldn't you have a "QSO" with a "NO CODE" Tech? Now, if the question were a QSO with one on a band he wasn't licensed to use, then the answer "could" be NO. BUT - if he has a "Control Operator" there with him to allow his use of that band, then by all means - the answer is still "yes".

Its all in how it is looked at. Too many people split hairs.....

How did you intend feeding it? Will the feedline look like a vertical
conductor, much like a metal support pole would?

When you feed your (halve wave) inverted V in the middle (top) via a balun, there will be no difference.

When you feed it at one end (with respect to ground) there will be some asymmetry in the antenna causing some net effect in the metal post. As long as the wire does not touch the post and the post is in the voltage minimum, the effect on the radiaton pattern and efficiency is negligible. Maybe you have to adjust the length a little bit.

> PS: I noted your throw away comment that time is of the essence,

Owen,

I appreciate your advice.

Just glad I'm not your neighbor.
I'm certainly not your errant student.

There are some elmers out there and then there are responses as above.

If you feel it is beneath you to respond, then by all means don't waste
your time responding. This is all too familiar.

For the record, I did not have deviating from G5RV specs as part of my
"design" and, as a first attempt, I wanted to avoid higher order issues
such as the arcane bickering about water on a transmission line.

Frankly, from a newbie perspective, so much controversy over such issues
calls into question any science that is behind so many assertions and
counter-assertions. If so much depends upon water on the line, then how
important can velocity factor be? This is said only partially in jest.

In my mind MIS-application of science is far worse than its non-application.

I think a good engineer would agree with me. Would you?

John
AB8O
not an engineer

PS
Cecil, your advice is more on the mark for me and I appreciate it. I'll work on velocity factor and EZNEC for the next project...if time allows. I'm proud to say that this is my hobby but it's not my career.

They had rows and rows of parts, and the rest of the store looked more like CC than RS. All I know is that an experimenter in Ottawa could get a lot of stuff that he/she needed.

And that's okay by me.

Which is why it was said, for many centuries, I suppose, that it's
speech that separates us from the animals. (We're a lot less visually
oriented than a lot of other species.)

I have listened to Turkish for years. Being able to make out a few
words does nothing for me.

But there are a lot of Turks who feel otherwise.

Your insularity is showing.

The major lobe is a very large portion of the total power, it has been
figured out but I doubt if anyone wants to figure it out again for any
particular yagi. I know I could care less, but it is obvious from
looking at the plotted radiation patterns that sidelobe power is very
small amount easily in the 2% ball park of the total amount. Of course
some yagis will be better at concentratining the power in the main
lobe than others. By the way ther is 3d yagi antenna pattern
information available. Just find plots for the antenna mounted
horizontally and vertically. This is something almost any antenna
simulation program can provide.

Dollar for Dollar DB for DB i would errect a Curtain antenna. It
outperforms Rhombics in all aspects of design and construction.
Considering that the 4 poles of a Rhombic can be used to build an
Array that will cover the globe, have equal or greater gain that would
make the curtain antenna a better choice. I suppose thats why just

about ever shortwave station in the world uses them!

If you want an opinion of a station who has used and is still using stacked rhombics ask Ian VK3MO. He will tell you thats his 6 wavelength perside rhombic is a terrible general purpose antenna. Since his antenna is fixed on new York he finds that quite frequently the propagation path rarely comes in on the direct computed bearing. He loses 10 to 20 db having his sharp rhombic. His rhombic does not have sufficient azimuth diversity since the 3db horizontal beamwidth is so narrow.

You also wont have the problem of finding a termination resistor, a decent globar one anyway. See w8ji.com or look at TCI's web page. Its one hell of a antenna. I am surprised nobody in ham radio has installed one, considering the large number of 200 ft towers in the world. When radio Switzerland closed down there was a special even ham station on air using a rotable 300ft high curtain, oh what a signal 24 dbi produces with a 100 watts! Now if you know of a stacked array that uses 4 mono band or other stacked antennas that cal deliver greater than 20dbi thats not a laser beam let us all know. I tried to come with such a stack using 6 log periodics using 42 ft booms on a 200 foot tower. It deliver such gain on the higher frequencies but fell short on 13mhz. The curtain will do it with a lot less expense.

What's wrong with that, if it helps motivate people to be better hams.
Unfortunately, most here don't want better hams.

No, numbers are decreasing because ham radio has been dumbed down so
having a ham license isn't worth anything anymore and people are leaving.

If you used 300 ohm ladder-line, like The Wireman's
#561 or #562, you did indeed deviate from G5RV specs
by making the ladder-line length equal to 31 feet.
For that particular transmission line, 1/2WL on 20m
is around 28 feet.

thanks all, well feedline aside i was only up to the 'mounting' phase
wondering just in theory at that point what it would do (fiberglass vs
metal)

i supposed i would have gotten myself into trouble w/the next question
whats the best way to mount the coax to min it 'interfering' w/the
antenna itself if the ans to the above was fiberglass

my thoughts woulda been to feed it in the center

just really trying to both figure the best performance and trying to
get a mental picture of whats going on the consequence wise

Code testing is absurd. The government shouldn't be in the merit badge
business.

If you really need a merit badge to hang on the wall, listen to W1AW
during a qualifying run....

Yes, and thanks
I actually emailed the supplier as there are no markings at all
indicating type on the ladder-line cable, but based upon description, I
have the 300 ohm line. Per your advice, I'll try shortening the
transmission line. Yours (and even Owen's) advice are always appreciated.

I simply won't be belittled or badgered, well, for ANY reason.

I really do listen to you guys, but practicality and time constraints
rule the day.

You seem to have it mostly covered, so I have only a couple more
suggestions...

The power cord has to run through a hole you drilled in the firewall.
If you snag the heater core, you have to go back to CB for three more
years. If you forget to use a rubber grommet and the cord shorts out,
add another year.

The antennas are installed with a drill, not a magnet or a clamp. If
you use a magnet mount, then drill a hole next to it for the coax
cable, you're only half-way to hamdom.

If your car doesn't veer at speeds over 35mph, your antennas aren't big
enough. Get the BIG Hustler coils and drill a 3/8" hole in a 16" pizza
pan for higher Q. But don't use an NMO mount for this setup.

Wireman's data for #561 and #562 shows vf=0.91, and for #563, vf=0.66.

I have found wide variation in line construction and hence vf of
nominally 300 ohm line, and suggest that it is worth measuring.

This information is not new, G5RV wrote "If it is desired to use 300
ohm ribbon type feeder for this section, it is strongly recommended
that the type with "windows" (ladder line) be used because of its much
lower loss than that with solid insulation throughout its length, and
its relative freedom from the "detuning" effect caused by rain or
snow. If this type of feeder is used for the matching section,
allowance must be made for its velocity factor in calculating the
mechanical length required to resonate as a half-wave section
electrically at 14.150 MHz. Since the velocity factor of standard 300
ohm ribbon feeder is 0.82, the mechanical length should be 8.5m (28
ft). However, if 300 ohm ribbon with "windows" is used, its velocity
factor will be almost that of open-wire feeder, say 0.90, so its
mechanical length should be 9.3m (30.6 ft)."

Talking about the physical length of the so-called matching section
without knowing the velocity factor of the actual line is incomplete,
it is the electrical length that matters.

I use #562 on my 20m rotatable dipole. Its VF measures
very close to 0.8. I needed the accuracy because I
vary the length of the feedline in order to resonate
the system on 20m-6m.

> simulation program can provide.

Like other I didnt understand the equestion as origionally posted
either. This was probably due to your false statement requardinding the
efficency or lack there of as you define efficentcy
of a yagi antenna. AS you say that you can take a look at an antenna
plot see that it is obviously inefficent without showing the mathmatics
I can look at one and tell you it is very efficent per your own

definition without giving the numbers. I can only assume you are confused by the fact the plots are drawn with a LOG scale as opposed to a linear scale. If drawn using a linear scale the side lobes would be 1/100 to 1/1000 the size of the main beam. If you dont want to take my word for simply take any yagi antenna plot and redraw it to a linear scale.

KSBD = Norton AFB They had RC-135's, wx recon.

Continuous Weather Watch would post an hourly observation, and
intermediate observations as various parameters crossed their
thresholds, usually an ALSTG local when conditions were stable.

Basic Weather Watch would examine the elements every 20 minutes and
post intermediate observations as various parameters crossed their
thresholds.

NOTAMS travelled the wx TTY circuits in the Air Force and the Army. We ripped them off and handed them to BASOPS. They posted them in the flight planning rooms.

Art

You are obviously much smarter than every one here combined. So I will leave it up to you to design the antenna(s) that no one has been able to come up with before this miracle antenna you envision. The tens of millions of man hours we have put into antenna developement cannot possibly equal your intelligence.

Prove everyone wrong. Go ahead. We're waiting.

Source record: 52009

In order, I like my HP15C, HP11C, and way behind HP48SX. And then there is my HP25.

I originally purchased an HP35, then an HP45, then an HP25, then finally an HP11. Which was so tough it got run over by a NY DOT dump truck and had merely a crease above the LCD display. And is still in use 25+ years later.

I purchased the HP15C as new when I thought the 11C was lost. Fortunately it was not. So I ended up with both (eventually).

I purchased a 48SX at a hamfest for $75. It seemed a good deal at the time, although I had to wait about a year for the heavy tobacco smoke it had absorbed to dissapate.

I still like my 15C the best. And it is still on it's second set of cells since 1982, impressive.

So, what calculators do you like best?

And, of course, why.

I am with you Tom, I like / prefer the HP calculators and have used
them since before the portable models you mentioned.

Right now, I have a HP42S with me on holidays, but I usually use a
'48GX at home.

You may have seen my adaptation of Clint Eastwood's quote when someone
asks me "who says so", and I reply "me, and two of my friends, Mr
Hewlett and Mr Packard".

However, I use a calculator for only a small percentage of problems
solving nowadays, there are better tools for most problems. I don't
have to reach far for a HP calculator, wouldn't be without it, but
most of the work is done using other tools.

I also started with an HP35, then 45, and went from there to an HP41CX. That was the nicest calculator I've ever had, and I flat wore it out. I was late getting a PC, but put the 41 to use in solving everything from iterative network problems to antenna patterns, self and mutual impedance calculations, phased array feed systems, you name it. The functions I most used were right there on the keyboard, available with a couple of keystrokes at most. Programming with the assembly-like language was fast, easy, and to me, intuitive. I ended up with a very large library of programs of all kinds.

Its replacement, an HP48GX, is a disappointment in every way but one. The person or people who dreamed up the programming system were totally indoctrinated, like so many of today's software engineers, that object oriented programming (OOP) is the best and only solution for every possible problem. Consequently, creating even a simple program is terribly time consuming and the result is worse than the worst GWBASIC spaghetti code I've ever seen. It's horrible! And while it can be highly customized, the learning curve is steep. Without customizing, just changing the number of displayed decimal points from 2 to 3 involves 5 keystrokes and waits of several seconds. I still don't know of a quick and easy way to swap the values in the x and y registers, although I honestly haven't looked hard and am sure there's a moderately simple way.

Its single redeeming feature, which keeps me using it daily, is the facility with which it handles complex numbers. I can mix and match real and complex numbers, add, multiply, take the square root, trig functions, everything, just as easily as with purely real numbers. I can swap between viewing in rectangular and polar notation in a second, and enter complex numbers in either form. For the kind of calculations I do very frequently, it's terrific. But if I didn't do a lot of calculations with complex numbers, I'd give it a 0.5 on a scale of 10.

Hi Tom,

A Rockwell (model unknown) was first in 1974. It was followed by an
HP16C (software oriented - lots of bits resolution). The Rockwell
was replaced by an HP20S. EasyCalc 1.22 for the Palm Tungsten
(shareware) - it does both scientific and bit logic.

The Palm is closest to me (naturally), the HP20S is under the display
here; the 16C is in the office (had to get up and toggle the power to
see if the second set of batteries still held a charge, they do -
after a thump or two to wake them up).

My all time favorite is the HP32S. It has a lot in common with a whole bunch of other HP RPN scientific calculators, but it hits the perfect balance between features and keyboard clutter. It also has one letter program prompts that are very handy to remind you what bit of info you are expected to supply to a program.

For instance, I calculate my work day in tenths of hours with a program I call up by hitting XEQ T (for time). It asks S? I input my start time (with a decimal point between hours and minutes o'clock). I hit RS (run stop) and it asks Q? and I enter my quitting time. It asks L? and I enter the duration of my lunch break. And it replys with H=hours.tenths of hours. These simple alphabetical prompts make it a lot easier to remember what an almost forgotten program wants and supplies, without being a chore to program or needing a small character display.

>HP16C (software oriented - lots of bits resolution). The Rockwell

At a time when my occupation was a System Programmer on IBM Large
Systems, and I spend too much of my life reading / analysing dumps
(mostly I must admit COBOL app programmers causing S0C7), I rang the
local HP calculator supplier for a price on a HP16C.

The chap greeted me immediately with "Well, you are a person of
distinction buying a HP16C, can I tell you about it?". I told him that
wasn't necessary, I have been using one for a while, and I wanted one
for working at home, to which he replied "Well, as the owner of two
HP16Cs, you will be a person of considerable distinction".

I always wondered how many calculators some people might have bought
from him, and what the subsequent steps were in the series
"distinction", "considerable distinction"... .

But seriously, and at the risk of offending others, the HP16C still
stands IMHO as the ultimately flexible programmers calculator.
(Programmer to mean someone who programmes the metal.)

In fact the whole series HP11 .. HP17 were good, and such a break from
needing to carry a charger every where.

I used my HP16C just last week developing a PIC based stateful
controller for DowKey pulse latching coax relays (a seriously ham
radio task). Ah, we are not off-topic, that is antenna related!

Yes, it looks like 80m per leg is reasonable - 4 wavelengths at 20m
I did as you suggested in terms of modelling the sag and it didn't seem
to upset the pattern greatly.

I can put the antenna over the house but I'm not sure if the extra
feeder loss would outweigh the advantages. Might not be too bad with 600
ohm or greater feeder.

That's a problem, which is why I had thought of only 4 wavelengths per
side. NEC says it would be about 15 degrees wide on 20m.

>
> You also wont have the problem of finding a termination resistor, a

I was going use it unterminated to begin with. Aimed at Europe, the
other end points at Central America so I'd be surprised if I had
problems covering both those areas at the same time.

How are they at VHF/UHF? For Field Day, I usually do 2M & 440 FM voice with very large vertically-polarized yagis. What am I going to get with a rhombic? Horizontal polarization, I'll bet, except maybe the whole rhombic can be rotated 90 degrees to transmit/receive a vertically-polarized signal.

I really want to try some experimenting, since 5 - 10 wavelengths of 440 is doable in my backyard using sticks guyed up with twine. What about UHF television reception? This could get interesting.

Might not be a problem for 100W - I'm on solar power and don't want to have to fire up the generator to power a linear :)

I found a strange thing with NEC in terms of multiple lobes. At 20m, NEC gave me a nice main lobe with the antenna at 15m but at 10m, there were two lobes about 30 degrees apart. I played with the height to see how it changed the lobe pattern but the results didn't make sense. The two lobes remained until the antenna went to a certain height, then one extra millimetre in height, and it went straight back to one main lobe.

Something that I saw done on commercial sites with high power
transmitters is to run a feedline down from the termination end of the
rhombic and run it underground for a while. If the loss is sufficient,
you don't even need the terminating resistor.

Very small difference all the way around.
I prefer metal masts because they are better lightning
returns. I'd rather have the metal mast taking the brunt of
the strike to ground rather than the feedline of an antenna.

> Thanks for your help.

There are loads of free softwares that will do that plus all the other
usual modes. No need to waste money on that, unless you have no
computer and sound card. Like the others say, most code readers
are not that great, and there is little difference from a standalone
box,
or just soundcard software. The brain is a much better reader.
I'd use it if you actually want to learn or improve CW skills.
If I were to use the puter, I'd rather work PSK or whatever.. It's
much more robust that using a puter for CW work.

Message-ID: <1159617185.706177.101440@h48g2000cwc.googlegroups.com>
Source record: 51930

Hi oM
I'm Pasquale IW0HEX, I live in Rome, ITALY
I bought a tribander antenna, Cushcraft X7, second hand (used) from OM
in South Italy.
Now I have 2 manuals of this antenna, one original and one download on
cushcraft homepage by internet.
There are some difference into 2 manuals about element's lenght.
In details :

Element Original manual (8/98) Download manual (12/97)

1 220" 220"
2 147-1/2" 147-1/2"
3 205-1/2" 208" (difference !!)
4 140" 137" (difference !!)
5 111" 111"
6 83" 86" (difference !!)
7 75" - 7" - 29" 77" - 7" - 35" (difference !!)

Last element (7) is trapped so it's divided in 3 parts (2 traps)

My question is : which are the rights lenghts ?????
Who has installed this antenna can help me ????
Tnx in advance.

73s Pasquale IW0HEX

Telephony has saved magnitudes more lives than CW.
If you are CW only, you are not properly equipped
to even attempt to save lives.

hi

I was wanting to dispel some myths about connector losses

lets assume my worst case freq 450mhz LOW /week singal work

lets assume my worst coax is ether lmr400 or 600 (not imp)

so naturally i'd use typically N connectors

how much do i lose if I screw in a right angle adapter?

in general at the base of a radio

and same question say i want to join to lengths of coax and use a
small stubby f/f N connector adapter ??

lose going from a DIN to an N via a adapter?? at radio and 'inline'

joining 2 coax lengths

some say the loss is actually neg some say it's going to add up and
the insertion loss could easily go over 1/2 db i dunno

exactly how good/bad is it?

and where can u get some good low loss adapters (i know of ampenol) I
bought some unknowns at a flea market and they had great loss to which
in that case i attribute to just poor quality

thanks to all those in advance that help me put the hamster back on the
wheel

Hmmmmmm - my how we belabor a point. MAYDAY IN CW = SOS..... SOS is
usually sent in those cases. SOS for the CW and Mayday for radiotelephone.
MAYDAY is "also" asked about in some RadioTelephone license exams for
"marine" use and is even becoming part of the Fire service. There is a test
specifically for "Mayday" and its uses. Mayday is "generally" used in
"airplane" emergencies.

My comment would be on the right angle N connectors. They vary dramatically. My area of interest is 1296MHz EME where any loss before the Feedhorn LNA shows up easily. I have an HP network analyzer and qualified a number of right angle N's. In general the adapter with a square block at the elbow were fine- under -0.03 dB. The gradual bend (called a sweep in plumbing terms I believe) had unacceptable return loss and much higher loss (sorry, no figures there).

Hello Owen,

You are right, feeding in the middle is good, your feed line is in the symmetry plane, where you have no E-field component parallel to your feed line. The line itself will not distort the radiation pattern.

When it is a halve wave mono band antenna I would use a coaxial feeder with balun (current mode balun with ferrite cores for example).

When the antenna has to work over multiple bands, you get problems with the impedance when your dipole is a full wave. Matching the coaxial feeder/balun combination will make almost sure all your power will be wasted in the form of heat in the balun and or the coaxial feeder. In that case I would prefer a symmetrical line (can have extremely low loss) and a symmetrical tuner.

When one end of the dipole is close to ground or a large metal structure, you may feed the dipole at that end as an alternative. When your dipole is a multiple of halve a wavelength, the input impedance at the ends is in the high kOhm range. So you will have a relative low feed current and therefore also low ground current (so the ground can be relatively bad).

I hope this and the other replies will help you to make good decision on what to do.

Wim
PA3DJS.

>hi
>
>I was wanting to dispel some myths about connector losses

Hi Myles,

They are largely myths. The true fact of the matter is in quality of construction and selection of materials. However, even there with a dedicated connection that is wrapped against the environment, a cheap materials connector will work as well (still, it must have good construction).

>lose going from a DIN to an N via a adapter??

That's a new one on me. There are a lot of DIN standards.

>some say the loss is actually neg some say it's going to add up and
>the insertion loss could easily go over 1/2 db i dunno

Negatives add up to bigger negatives. The point of negatives is in application. You can say a connector is specified at -0.1dB or that it has 0.1dB loss - same thing. To say it has -0.1dB loss is something of an anachronism, but it is often encountered.

>exactly how good/bad is it?

Same dependencies I've already mentioned. You probably couldn't measure it without sophisticated tools.

>and where can u get some good low loss adapters (i know of ampenol) I
>bought some unknowns at a flea market and they had great loss to which
>in that case i attribute to just poor quality

I would then have to ask: How do you know they had "great loss?" 1dB loss at the connection point would be as hot as a Christmas tree lightbulb for 100W passing through it.

>My question is : which are the rights lenghts ?????

Hi Pasquale,

Literally, it depends on when the antenna was built (which standards
did it use).

The practical answer is: the proper length is what you measure after
tuning it. Split the differences and start tuning from there.

My first calculator in the late '50s was a Lafayette 99-71029 log log duplex decitrig bamboo 12" rule followed shortly by the Pickett aluminum 6" pocket rule. Followed eventually by the HP-35 and thereafter by the Rat Shack Model II with a whopping 64k of memory.

Current favorite for serious design work is the Athlon 64 bit 3200. For desk quick and dirty, the Casio $8 fx82l from Staples is more than enough. Followed, of course, by the Pickett when the power goes out.

My x-xyl made me up a little shadow box with the Pickett mounted in the center and an engraved plaque that says "In Case Of Emergency Break Glass".

There are 2 manuals version......

one on August 1998 and one on December 1997.

On cucshcraf site there is version on 12/1997 but reading this webpage
X7 reviews

http://www.gm4nhi.freeserve.co.uk/X7review.htm

it's seem that right version is on manual 8/1998 (recent version)
I wrote element lenght in my first msg....
Which is the rights version ?

I suppose the most recent, so August 1998.
Pse, let me know.

Hi Pasquale,

The problem is which manual was the antenna designed FOR?

If you do not know when the antenna was built/sold, then "which
manual" does not make much sense.

As offered, split the difference (choose lengths half way between
different lengths offered) and tune the antenna. The antenna is
probably NOT going to be in tune by simply following dimensions.
Dimensions are simply a starting point. Few antennas are erected in a
tuned condition (they rarely work the first time).

This means you will have to
1. put it together,
2. tune it or build to dimensions (or split dimensions),
3. put it up,
4. measure SWR across frequencies and bands, and
5. take it back down and change dimensions.
Repeat 3/4/5 until all bands measure to satisfaction.

Alternatively, erect the antenna pointing up. This is so you have
access from the ground to make the first tunings. This saves putting
it up and taking it down too much.

Tom et al-

You guys are out of my league. Back when I needed a good calculator, I
couldn't afford the new HP-35. By now, I've forgotten how to use the
slide rules in my collection.

I do have a Palm PDA. There is a freeware reverse-Polish program for it
called Kalk by Holger Klawitter. It is available at
http://www.klawitter.de/palm. I doubt it will match the fine HP
instruments you mention, but you may want to have a copy if you spend a
lot of time with your PDA.

Leaving aside the little sliderule that I used as a child, the larger ones latter, and the huge spiral job at University, I started with a desk top Burrows (sp?) with nixie tubes and lots of RFI (still have it). In 1972 when the HP35 was announced, I bought two. One for my wife to use. They were so expensive that we had our names engraved into the case. Still have them and they still work.
The HP25C was nice, the HP15C was near-optimum (and still kept as a backup), but I find the HP48 series to be the most useful. I keep one at work and one at home and at least one new-in-the-box. As Roy has indicated, the HP48 does an excellent job with complex numbers including solving systems of linear equations with complex coefficients. The HP48 also allows the easy storage of non-linear equations with many variables and allows one easily to solve for any one variable. I have not used more than a few % of the calculator's capability. Only one faculty member in my ECE department uses other than an HP calculator (a young instructor).

For some time, I used the HP calculator with a built in printer and magnetic card reader. Cannot remember the number. I did use its programming capabilities. One program that I wrote - to get in the obligatory antenna reference - was a program to estimate the bore-site gain of a rhombic antenna - HP published it in one of their many books.

My students are required to master the use of a calculator in circuits and electronics. The HP48, and now the HP49, is the best for those purposes. However, many students limp along with TI calculators. Some of them do not have ready access to a reciprocal key. Try finding the impedance of three impedances in parallel without a reciprocal key. With an HP48/49 the task is trivial.
The ability with one stroke to combine an imaginary part with the real part of a complex number is an example of how well suited the HP48 is to EE work.

As part of my syllabus, I give examples of the type of calculations that the student's calculator must be able to perform. Because discerning students now purchase HP49 calculators, I also have one of them. Seems not to be as rugged, but it is much faster.

I can not speak to the programming system of the HP48 as I have not used same - though the solve scheme of complicated equations gets a regular workout. Swapping is effected with two key strokes: (0,0 column, row starting in the lower left) 0,3 and then 6,8.

It was always clear that when the engineer founders of HP left, the company would flounder. Thank goodness much of the important part was spun off.

The answer to the original question: buy an HP49 - spend some quality
time learning to use it. In terms of purchasing cost, an HP49 is very low
cost compared to a good slide rule.

thanks rich and dale

appreciate the help!

rich i new the connector was bad cause i noticed less power on my meter
swapped it out, got a few lemons :(

dale: wow i always wondered about those elebow square designs ,
not sure what you ment by the 'gradual' bend ones i've seen the
'standard' right angle connectors but werent' 'gentle' they were 90
hard bends is this what you ment?

or did you ment if you simply made a gentle arc in the coax vs using
a rt angle connector tht a good connector rt angle adapter was better

i'd like to put a few adapters both F/F and rt angles on but didn't
want to do it if it would kill me loss wise

thanks

I started with my name engraved on a K&E Log Log Duplex Decitrig. But that was over 20 years before I bought an HP35. When the programmable HP65 appeared, I was in heaven. I bought every solutions book and even wrote and submitted a few myself. Of course the HP67, HP41CX and HP42S saw steady use, each in its day. When the HP48GX came out, I eagerly snapped one up, and after about a week of frustration I wrote a terrible letter to HP, decrying their "start over with a blank sheet of paper" approach. I guess those are the 4-bangers one of you mentioned above. After retiring from my engineering position, I found quite a few HP12C at various flea markets, and snapped them up - - you need a calculator at every desk, coffee table, and work bench in the house and every car in the garage, don't you? But then, an amazing machine hit the (flea) market - - the HP17B, and its so welcome follow-on the HP17BII with Reverse Polish and "solve" functions. Of course

there were HP27S, HP11C and an HP15C found at various times, too, but currently the HP12C at every elbow, and at my main computer table the HP42S for complicated things like Log Periodic antenna design, and Solar Array calcs and my trusty HP17BII for all single expression solutions. It has been an eventful and enjoyable life.

Pasquale, the measurements you list in the original manual is the same
as in my manual, the date on my manual is 5/99.
I put the antenna up about a year ago and using those measurements it
works great without any tuning.
The tuner in the radio will also tune it on 24 and 28 Mhz, I also was
able to tune it on 40 meters.

Source record: 51963

Prior to 1972 I used a K&E and then a Pickett & Eckel slide rule and a Smith Chart calculator slide rule.

But I purchased an HP-35 when it first came out. Then the HP-45, and a 55 that had a neat timer. After retiring in 1980 I purchased the HP-34C and the 15C. One of my sons worked for HP for 25 years, and while there he purchased two HP-42S, one for me. They all go with me wherever I go.

I tried to use someone elses TI one time, but after using RPN I couldn't make the darn thing work. The RPN works just like writing down the problem and solving it with a pencil.

That Polish guy Lucashowicz (sp?) is my hero!

Blowcode can, in his small mind's imagination, do all sorts
of things.

Here's a "plain and simple fact" of possible probables in
case of anyone ACTUALLY dying or needing help:

1. By telephone, wired or cell: Dial 911, the universal,
manned 24/7 emergency number. In turn, the 911 operator
will communicate with the appropriate agency by wire
or radio (there are 3 basic radio bands for public
safety radio services in the USA, one more coming).
There is one cell phone for every three citizens in the
USA. Speed as fast as a 911 conversation.

2. By - gasp - Citizens Band Radio Service transceivers in
urban areas. CB radio users out-number amateurs by 4 to
5 to one. Considering that some radio amateurs have to
work for a living and are not AT their ham radios but
highway truckers are both working and with their CBs,
the virtual ratio is probably double 5:1. Probability
of return to first communication about help is high
considering that many CB transceivers have guard
receivers always tuned to the emergency channel. Speed
of that is variable, may take three times longer than a
conversation with a 911 operator.

3. If flying there are two basic ways to indicate help.
Overland airways routes will have ATCRBS running and a
transponder "77" prefix code will generate a flag on
the ATC beacon display. On civil airways, 121.5 MHz
is the international universal emergency frequency
(243 MHz for military radio). Speed of either is a bit
longer than with 911 operator calling but quite fast.

4. On the water, in inland waterways and harbors, there is a VHF FM channel for emergencies but common in-use frequencies would get attention for real calls for help. GMDSS is available on ships over deep water as well as an HF radio voice channel for international maritime distress calls. Since maritmers are noted for adherence to SOLAS (Safety Of Life At Sea), the response would be fast.

5. On land, lacking cell coverage (rare now) but on or near highways, there is high probability that any motorist or trucker would have a CB or possibly a business vehicle with a business radio would be passing (PLMRS vehicular radios are quite common with small and large businesses). Any passing public safety agency vehicle would have a radio transceiver capable of directly contacting appropriate help. Farmers are increasing their use of private radios and might be nearby. FRS and GMRS HTs are also becoming more common for both private and business use. Speed of help calling would be variable depending on location, nearby vehicular traffic.

6. Lacking any of the above, one might look for a non-TV or non-CB antenna on a house...high probability of that belonging to a radio amateur. [such a search could take many hours, though] If the date and time corresponded to a ham contest time, the ham might not respond quickly. Even if the ham responded and began calling, there is no assurance that anyone would hear or pay attention to some emergency plea; that would violate the normal conversation that goes on in ham bands and cause much on-air disputes, further clogging calls for help. Speed of help calling is variable, anything from several minutes to many hours. Not that it matters since the victim already died after trying to get through all the ragchewing, self-styled radio police, and general cat-calling by other amateurs.

7. Blow Code is of NO help since he is not verified as a valid (or invalid) licensed radio amateur.

or you if you had to you could send ing sos or oso the later seems
likely to get you aid the fastest from the CW they will df you fast to
come and castise you for it and likely then well at least rennder first
aid as they take you to task for daring to misspell sos

4931. 20 M vertical ground plane antenna performance?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-09-30 21:39:16 UTC
From: Steve Reinhardt <stevereinhardt@noearthspamlink.net>
Message-ID: <euBTg.2222$121.1252@newsfe06.lga>
Source record: 51968

I'm looking at another antenna for 20M. I've got a partially folded indoor attic antenna which gets out fairly well, but it certainly is directional.
The ARRL handbook has had this design in it since they invented radio. It's often used at VHF, but seems a good candidate for this QTH. It's a 1/4 wave element over 4 1/4 wave radials at 45 degrees off horizontal, drooping to earth. My installation would be at ground level, with the base of the radiating element about 12.5 feet of the earth. Mechanically, it would be easy to put together, but I hate to waste the time if it's known to be a poor performer. I tried to use the EZNEC 4 demo, but 55 segments aren't enough to create a reasonable model of the physical layout, and I'm not smart enough to try a simplification.
So, has anyone done an analysis of this antenna? Would the performance be similar to a low mounted vertical dipole, or would the 4 radials offer a bit better performance so close to earth?
If there's an literature I missed, please point me toward it. Most of the antenna manufacturers refer to regular flat, on the ground radial systems, and except for some CB literature which has no technical basis for its recommendations, there's not any analytical data I can find. The best thing I found was at web.wt.net/~nm5k/acompari.htm for 10m applications, at 40 ft elevation.

73,
W1KF

I know from various documents written by amateurs that there is a lot of antenna related expertise within the Amateur Ccommunity (from which I believe many are professionals). Many times it is difficult to figure out who is telling "the facts".

Regarding classes, I am sure there are, but mostly are very expensive. In the Netherlands there are a few companies that offer courses on antenna design. Sometimes they are cancelled because of lack of attendees.

With respect to books, many books tell you how to build an antenna from a drawing (and not the theory behind it), other books tell you the theory behind it, but require differential vector calculus.

It took me many years to understand antennas at the same level as my electronic design activities.

Given all this, ¡I still like experimenting with antennas! I just finished a design for the coming "Jamboree on the Air" to be held during the weekend of 22 October (Scouting activity).

Best Regards,

Wim

Hello Steve,

Yes, a quarter wave radiator fed over 4 quarter wave radials is a good antenna, it performs almost equally as a vertical dipole. The main advantage over the vertical dipole is that you can mount it on top of a mast and you do not need a balun.

Because of the 4 quarter-wave radials, you will get a good virtual ground avoiding common mode current into you 50 Ohm coaxial feeder and or the mast. You do not need any further matching. Make sure that the ends of the radials do not touch ground. If the ends are close to ground, probably you have to shorten them a bit to account for the capacitive effect caused by the ground. I would recommend you to higher the feed point of the antenna.

When you want more gain and are able to do the construction work, you may extend to close to a 5/8 wave, you only need a series coil to do the matching. Using a halve wave radiator (fed over the 4 radials) is also possible, but the impedance is in the kOhm range and therefore matching is somewhat more difficult.

I hope this will help you.

Wim
PA3DJS
